

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (http://bmjopen.bmj.com).

If you have any questions on BMJ Open's open peer review process please email info.bmjopen@bmj.com

ABSTRACT

Introduction

The novel SARS-CoV-2 pandemic has provided a set of unique challenges for pediatric patients requiring emergency care across the globe. Reduction in pediatric emergency department (ED) usage during the COVID-19 pandemic has been widely reported, but no studies to date have consolidated and described what ramifications these reductions may have on neonatal and infant health. This scoping review aims to characterize the impact of the COVID-19 pandemic on infant emergency department visits and neonatal and infant health.

Methods and analysis

A comprehensive literature search will be conducted from March 2020 to June 2021 using the following databases: Embase (OVID), Web of Science (Clarivate Analytics), Medline (Ovid) and CINAHL (EBSCOhost). This scoping review will use a five-step framework to guide the selection, extraction and analysis of data from eligible studies, with an additional sixth step for clinical consultation. Studies in English reporting the effect of the COVID-19 pandemic on infant ED visits, as well as neonatal and infant health will be included for screening. Key findings will be reported according to the Preferred Reporting Items for Systematic Reviews and Meta-Analysis Extension for Scoping Reviews.

Ethics and dissemination

Research ethics board approval will not be required due to the nature of study design. The results of this scoping review will be disseminated through publication in a peer-reviewed journal and presentation at academic conferences.

Strengths and limitations of this study

- This scoping review will address the literature gap on the impact of the COVID-19 pandemic on infant emergency department visits and neonatal and infant health.
- Primary studies included in this review will compare data prior to and during the COVID-19 pandemic in order to accurately assess trend differences.
- A clinical expert will be consulted to inform the applicability of study results.
- Due to the novelty of the COVID-19 pandemic, primary studies reporting data on the subject matter are limited.

INTRODUCTION

In March 2020 the World Health Organization declared the novel Coronavirus (COVID-19) outbreak a global pandemic, which continues to affect millions globally ¹. As individuals restrict their movements, undergo mandatory social distancing, and work from home, hospitals around the globe are observing a reduced patient load in their emergency departments (ED) ². The Centre for Disease Control and Prevention reports a 42% decrease in ED visits in the United States based on weekly means, dropping from 2.1 million per week prepandemic to 1.2 million during the pandemic, with the steepest decrease reported in the pediatric patient population ³.

Several studies report a steep decrease in pediatric ED visits since the COVID-19 pandemic began ^{4–7}. A Canadian study of eleven pediatric centers reported a decrease in ED visits by 58% during the pandemic, compared to estimated rates ⁸. The literature highlights that reduced ED usage may be a result of increased lockdown measures, social distancing, and fear of contracting SARS-CoV-2 ⁵. Data from Korea highlights the association between increasing government restrictions and a reduction in the number of monthly ED visits ⁹.

Previous work detailing the effect of the H1N1 pandemic on infant health, morbidity, and mortality may offer insight regarding potential effects of SARS-CoV-2 infection in this population. Studies report delays in presentation to the ED during the H1N1 pandemic (2.8 ± 2.3 days) as well an increase in pediatric intensive care unit (PICU) admissions during this time compared to years prior (0.3% vs 0.1%; 95% CI 0.05%, 0.4%) 10,11 . Children younger than two years of age with a confirmed H1N1 diagnosis were reported to have an increased risk of hospitalization during this period (RR 3.3; 95% CI 1.80, 6.05) 10 . One population-based study in England reported the highest case-fatality rate in their infant (<1year) population, with a fatality rate of 151 per 100,000 cases of H1N1 12 .

To date, most studies have focused on collecting or retrospectively analyzing primary data to quantify the reduction in pediatric ED usage during the COVID-19 pandemic. The literature is lacking consensus on the implications of these reductions on infant health outside the context of a confirmed COVID-19 diagnosis, in the general infant population. Given what is known about previous pandemics precipitating adverse effects on infant health ^{10–12}, further knowledge synthesis is required to address the novel situation created by the COVID-19 pandemic. Our objective is to conduct a scoping review to characterize the effect of, and to better understand the impact of the COVID-19 pandemic on infant emergency department visits and secondarily, neonatal and infant health.

METHODS AND ANALYSIS

This scoping review will be conducted according to the methodological framework developed by Arksey and O'Malley and refined by Levac *et al* and the Joanna Briggs Institute (JBI) ^{13–15}. The steps outline by these frameworks are: (1) identification of the research question, (2) identification of relevant studies, (3) selection of studies, (4) charting the data, and (5) collating, summarizing, and reporting results. As recommended by Arksey and O'Malley ¹³, we included an additional consultation step with a clinical expert, to find additional sources of information and inform the clinical relevance and value of this review.

To help identify the main concepts of the primary review question, the Population/Concepts/Context (PCC) framework is suggested by the JBI ¹⁵. The specific PCC framework for this study is presented in **Table 1**. The primary research question for this review is: what is the current evidence reporting the effect of the COVID-19 pandemic on infant emergency department visits, neonatal, and infant health?

Table 1	l Po	pula	tıon-(Concep	t-(_`ont	text
---------	------	------	--------	--------	-----	-------	------

Table 1 Population-Concept-Context		
Population	All peer-reviewed journal articles including neonates (<28 days) and infants (<1 year) will be included.	
Concepts	Literature reporting on the frequency/rate and main reasons for neonate/infant ED visits during and before the COVID-19 pandemic will be reviewed. Literature reporting on infant outcomes; infant mortality including neonatal death (< 28 days) and infant death (< 1 year of age), main reasons for infant mortality, infant and neonate hospitalization, main reasons for hospital admission, pediatric or neonatal intensive care unit admission and length of ED visit and/or hospital stay will also be reviewed.	
Context	The context will be hospital emergency departments. The time-frame is before and during the COVID-19 pandemic (March 2020 and onwards). There will be no restrictions on geographical location.	

ED, emergency department.

Step 2: Identifying relevant studies

Our search strategy and database choice will be developed in conjunction with, and refined by a trained medical librarian. Four online databases will be searched, including: Embase (OVID), Web of Science (Clarivate Analytics), Medline (Ovid) and CINAHL (EBSCOhost). Key search terms were developed to capture literature related to the effect of the COVID-19 pandemic on infant ED visits, as well as neonatal and infant health. Truncation and Boolean were used to narrow, widen and combine search parameters as necessary. The finalized search strategies are available in online supplementary appendix 1. The literature search will be carried out in February 2022 and will be updated before the review is submitted for publication.

We agreed to the following eligibility criteria for the initial search:

- Type of publication: journal articles.
- Time frame: during the COVID-19 pandemic (March 2020 onwards).
- Study population: neonates (<28 days of age) and infants (< 1 year of age) presenting to the ED for medical attention.
- Study designs: Analytic epidemiological observational study designs (i.e. cohort studies, case-control studies or cross-sectional design studies), analytical ecological studies (i.e. time series studies), and systematic reviews with or without meta-analyses.

 We will exclude: case reports and series, editorials, commentaries, letters to the editor, abstracts, conference proceedings, book chapters, narrative reviews, non-English studies and any studies that do not compare outcome data collected during the pandemic with a time period prior to the pandemic.

Step 3: Study selection

Records from electronic database searches will be imported into Microsoft Excel to eliminate duplicates. Two reviewers (BO, MMH) will independently screen titles and abstracts to determine study eligibility based on predefined inclusion and exclusion criteria. A second screen of the article in full-text will be performed by two independent reviewers (BO, MMH) to ensure that studies fully meet inclusion criteria and report relevant data. Any discrepancies will be resolved by consensus or through a third reviewer (RF). The results of the screening process will be displayed by a Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram ¹⁶.

Step 4: Charting the data

Data will be extracted into standardized forms in Excel by two reviewers (BO, MMH) and checked for accuracy and completeness by a third reviewer (RF). Whenever necessary, the authors of the original study will be contacted for additional information and clarification of the data. Reviewers will resolve discrepancies through consensus or consultation with another study author (RF, YG). The data charting forms are available in online supplementary appendix 2.

Extracted data will include: 1) Bibliometric details: title, author(s), publication year, journal, 2) Study details: study design, inclusion and exclusion criteria, sample size, sample characteristics, setting, sample size included in analysis, 3) Primary outcome: changes in pediatric ED visits reported during and before the COVID-19 pandemic including numbers, percentages, frequencies, and reasons for change, 4) Secondary outcomes: changes in infant morbidity and mortality details, infant hospitalization, PICU admission, reasons for ED visits and hospital admission and length of ED visit or hospital stay during and before the pandemic.

Step 5: Collating, summarizing, and reporting results

The results from this review will be presented in tables, while pertinent bibliometric details and critical results will be described according to standardized scoping review methodologies. We will collate results exclusively from peer-reviewed journal articles and comment on heterogeneity of the reported results. Extracted data will focus on trends in infant ED usage during and before the COVID-19 pandemic, as well as the impact of the pandemic on infant and neonatal health parameters. Gaps in the literature will be highlighted, and supported by a consultation with a clinical expert in the field. The PRISMA extension for Scoping Reviews (PRISMA-ScR) checklist will be followed to report the results of this scoping review ¹⁷.

Step 6: Expert consultation

A consultation with a clinical expert will be sought to strengthen the rigor of the scoping review. Sharing preliminary results with the clinical expert will allow for discussion related to data interpretation, clinical applicability, and dissemination strategies. The clinical expert will provide academic insight beyond what is currently reported in the literature, assist with

identifying additional sources of information, and inform the clinical relevancy of the scoping review.

Patient and public involvement

The development of this protocol does not require patient or public involvement.

ETHICS AND DISSEMINATION

Ethics approval is not required by the institutional REB as scoping review methodology does not consist of primary data collection. Results from this scoping review will be presented at scientific conferences and be published in a peer-reviewed journal according to the PRISMA-ScR guidelines.

Contributors

YG and SWW conceptualized the study. YG, BO and RF generated and reviewed the inclusion and exclusion criteria. RS developed the search strategy in conjunction with authors YG, RF and BO. BO and MMH designed the data extraction tool. BO drafted the protocol for publication. YG, RF and MMH critically revised the protocol, and all authors approved the manuscript of this protocol for publication. We would like to thank Risa Shorr, medical librarian at The Ottawa Hospital for developing the search strategy and advising on appropriate databases for the review.

Funding

This research is supported by a Canadian Institutes of Health Research Foundation Grant (FDN 148438), a Children's Hospital of Eastern Ontario Research Institute Summer Studentship Award and a University of Ottawa Faculty of Medicine Summer Studentship bursary.

Competing interests

None declared.

Patient and public involvement

Patients and/or public were not involved in the design, conduct, reporting or dissemination strategies of the results of this investigation.

Patient consent for publication

Not required.

ABSTRACT

Introduction

The novel SARS-CoV-2 pandemic has provided a set of unique challenges for pediatric patients requiring emergency care across the globe. Reduction in pediatric emergency department (ED) usage during the COVID-19 pandemic has been widely reported, but no studies to date have consolidated and described what ramifications these reductions may have on neonatal and infant health. This scoping review aims to characterize the impact of the COVID-19 pandemic on infant emergency department visits and neonatal and infant health.

Methods and analysis

A comprehensive literature search will be conducted from March 2020 to June 2021 using the following databases: Embase (OVID), Web of Science (Clarivate Analytics), Medline (Ovid) and CINAHL (EBSCOhost). This scoping review will use a five-step framework to guide the selection, extraction and analysis of data from eligible studies, with an additional sixth step for clinical consultation. Studies in English reporting the effect of the COVID-19 pandemic on infant ED visits, as well as neonatal and infant health will be included for screening. Key findings will be reported according to the Preferred Reporting Items for Systematic Reviews and Meta-Analysis Extension for Scoping Reviews.

Ethics and dissemination

Research ethics board approval will not be required due to the nature of study design. The results of this scoping review will be disseminated through publication in a peer-reviewed journal and presentation at academic conferences.

Strengths and limitations of this study

- Peer-reviewed framework for scoping reviews (Arksey & O'Malley) was used to design this study.
- Selected studies will compare data prior to and during the COVID-19 pandemic to assess trend differences.
- A clinical expert will be consulted to inform the applicability of study results.
- Availability of relevant data in selected studies may vary per site.

INTRODUCTION

In March 2020 the World Health Organization declared the novel Coronavirus (COVID-19) outbreak a global pandemic, which continues to affect millions globally ¹. As individuals restrict their movements, undergo mandatory social distancing, and work from home, hospitals around the globe are observing a reduced patient load in their emergency departments (ED) ². The Centre for Disease Control and Prevention reports a 42% decrease in ED visits in the United States based on weekly means, dropping from 2.1 million per week prepandemic to 1.2 million during the pandemic, with the steepest decrease reported in the pediatric patient population ³.

Several studies report a steep decrease in pediatric ED visits since the COVID-19 pandemic began ^{4–7}. A Canadian study of eleven pediatric centers reported a decrease in ED visits by 58% during the pandemic, compared to estimated rates ⁸. The literature highlights that reduced ED usage may be a result of increased lockdown measures, social distancing, and fear of contracting SARS-CoV-2 ⁵. Data from Korea highlights the association between increasing government restrictions and a reduction in the number of monthly ED visits ⁹.

Previous work detailing the effect of the H1N1 pandemic on infant health, morbidity, and mortality may offer insight regarding potential effects of SARS-CoV-2 infection in this population. Studies report delays in presentation to the ED during the H1N1 pandemic (2.8 ± 2.3 days) as well an increase in pediatric intensive care unit (PICU) admissions during this time compared to years prior (0.3% vs 0.1%; 95% CI 0.05%, 0.4%) 10,11 . Children younger than two years of age with a confirmed H1N1 diagnosis were reported to have an increased risk of hospitalization during this period (RR 3.3; 95% CI 1.80, 6.05) 10 . One population-based study in England reported the highest case-fatality rate in their infant (<1year) population, with a fatality rate of 151 per 100,000 cases of H1N1 12 .

To date, most studies have focused on collecting or retrospectively analyzing primary data to quantify the reduction in pediatric ED usage during the COVID-19 pandemic. The literature is lacking consensus on the implications of these reductions on infant health outside the context of a confirmed COVID-19 diagnosis, in the general infant population. Given what is known about previous pandemics precipitating adverse effects on infant health ^{10–12}, further knowledge synthesis is required to address the novel situation created by the COVID-19 pandemic. Our objective is to conduct a scoping review to characterize the effect of, and to better understand the impact of the COVID-19 pandemic on infant emergency department visits and secondarily, neonatal and infant health.

METHODS AND ANALYSIS

This scoping review will be conducted according to the methodological framework developed by Arksey and O'Malley and refined by Levac *et al* and the Joanna Briggs Institute (JBI) ^{13–15}. The steps outline by these frameworks are: (1) identification of the research question, (2) identification of relevant studies, (3) selection of studies, (4) charting the data, and (5) collating, summarizing, and reporting results. As recommended by Arksey and O'Malley ¹³, we included an additional consultation step with a clinical expert, to find additional sources of information and inform the clinical relevance and value of this review.

To help identify the main concepts of the primary review question, the Population/Concepts/Context (PCC) framework is suggested by the JBI ¹⁵. The specific PCC framework for this study is presented in **Table 1**. The primary research question for this review is: what is the current evidence reporting the effect of the COVID-19 pandemic on infant emergency department visits, neonatal, and infant health?

Table 1	1 Popul	lation-C	oncept-C	ontext
---------	---------	----------	----------	--------

Table 1 Population-Concept-Context		
	All peer-reviewed journal articles including	
Population	neonates (<28 days) and infants (<1 year) will be	
	included.	
	Literature reporting on the frequency/rate and main	
	reasons for neonate/infant ED visits during and	
	before the COVID-19 pandemic will be reviewed.	
	Literature reporting on infant outcomes; infant	
	mortality including neonatal death (< 28 days) and	
Concepts	infant death (< 1 year of age), main reasons for	
	infant mortality, infant and neonate hospitalization,	
	main reasons for hospital admission, pediatric or	
	neonatal intensive care unit admission, high	
	dependency unit admission and length of ED visit	
	and/or hospital stay will also be reviewed.	
	The context will be hospital emergency	
	departments. The time-frame is before and during	
	the COVID-19 pandemic (March 2020 and	
Context	onwards). There will be no restrictions on	
	geographical location.	

ED, emergency department.

Step 2: Identifying relevant studies

Our search strategy and database choice will be developed in conjunction with, and refined by a trained medical librarian. Four online databases will be searched, including: Embase (OVID), Web of Science (Clarivate Analytics), Medline (Ovid) and CINAHL (EBSCOhost). Key search terms were developed to capture literature related to the effect of the COVID-19 pandemic on infant ED visits, as well as neonatal and infant health. Truncation and Boolean were used to narrow, widen and combine search parameters as necessary. The finalized search strategies are available in online supplementary appendix 1. The initial literature search will be carried out July 15th, 2022 and the study will be completed September 15th, 2022.

We agreed to the following eligibility criteria for the initial search:

- Type of publication: journal articles.
- Time frame: during the COVID-19 pandemic (March 2020 onwards).
- Study population: neonates (<28 days of age) and infants (< 1 year of age) presenting to the ED for medical attention.
- Study designs: Analytic epidemiological observational study designs (i.e. cohort studies, case-control studies or cross-sectional design studies), analytical ecological studies (i.e. time series studies), and systematic reviews with or without meta-analyses.

We will exclude: case reports and series, editorials, commentaries, letters to the editor, abstracts, conference proceedings, book chapters, narrative reviews, pre-print literature, non-English studies and any studies that do not compare outcome data collected during the pandemic with a time period prior to the pandemic.

Step 3: Study selection

Records from electronic database searches will be imported into Microsoft Excel to eliminate duplicates. Two reviewers (BO, MMH) will independently screen titles and abstracts to determine study eligibility based on predefined inclusion and exclusion criteria. A second screen of the article in full-text will be performed by two independent reviewers (BO, MMH) to ensure that studies fully meet inclusion criteria and report relevant data. Any discrepancies will be resolved by consensus or through a third reviewer (RF). The results of the screening process will be displayed by a Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram ¹⁶.

Step 4: Charting the data

Data will be extracted into standardized forms in Excel by two reviewers (BO, MMH) and checked for accuracy and completeness by a third reviewer (RF). Whenever necessary, the authors of the original study will be contacted for additional information and clarification of the data. Reviewers will resolve discrepancies through consensus or consultation with another study author (RF, YG). The data charting forms are available in online supplementary appendix 2.

Extracted data will include: 1) Bibliometric details: title, author(s), publication year, journal, 2) Study details: study design, inclusion and exclusion criteria, sample size, sample characteristics, setting, sample size included in analysis, study period 3) Primary outcome: changes in pediatric ED visits reported during and before the COVID-19 pandemic including numbers, percentages, frequencies, and reasons for change, 4) Secondary outcomes: changes in infant morbidity and mortality details, neonatal intensive care unit (NICU) admission, PICU or high-dependency unit (HDU) admission, infant hospitalizations, reasons for ED visits or hospital admission and length of ED visit or hospital stay during and before the pandemic.

Step 5: Collating, summarizing, and reporting results

The results from this review will be presented in tables, while pertinent bibliometric details and critical results will be described according to standardized scoping review methodologies. We will collate results exclusively from peer-reviewed journal articles and comment on heterogeneity of the reported results. Extracted data will focus on trends in infant ED usage during and before the COVID-19 pandemic, as well as the impact of the pandemic on infant and neonatal health parameters. Gaps in the literature will be highlighted, and supported by a consultation with a clinical expert in the field. The PRISMA extension for Scoping Reviews (PRISMA-ScR) checklist will be followed to report the results of this scoping review ¹⁷.

Step 6: Expert consultation

A consultation with a clinical expert will be sought to strengthen the rigor of the scoping review. Sharing preliminary results with the clinical expert will allow for discussion related to data interpretation, clinical applicability, and dissemination strategies. The clinical expert will provide academic insight beyond what is currently reported in the literature, assist with

identifying additional sources of information, and inform the clinical relevancy of the scoping review.

Patient and public involvement

Patients and the public were not involved in the development of this protocol.

ETHICS AND DISSEMINATION

Ethics approval is not required by the institutional REB as scoping review methodology does not consist of primary data collection. Results from this scoping review will be presented at scientific conferences and be published in a peer-reviewed journal according to the PRISMA-ScR guidelines.

Contributors

YG, SWW and MW conceptualized the study. YG, BO and RF generated and reviewed the inclusion and exclusion criteria. RS developed the search strategy in conjunction with authors YG, RF and BO. BO and MMH designed the data extraction tool. BO and MMH drafted the protocol for publication. All authors critically revised and approved the manuscript of this protocol for publication. We would like to thank Risa Shorr, medical librarian at The Ottawa Hospital for developing the search strategy and advising on appropriate databases for the review.

Funding

This research is supported by a Canadian Institutes of Health Research Foundation Grant (FDN 148438), a Children's Hospital of Eastern Ontario Research Institute Summer Studentship Award and a University of Ottawa Faculty of Medicine Summer Studentship bursary.

Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) Checklist

SECTION	ITEM	PRISMA-ScR CHECKLIST ITEM	REPORTED ON PAGE #				
TITLE							
Title	1	Identify the report as a scoping review.	1				
ABSTRACT							
Structured summary	2	Provide a structured summary that includes (as applicable): background, objectives, eligibility criteria, sources of evidence, charting methods, results, and conclusions that relate to the review questions and objectives.	2				
INTRODUCTION							
Rationale	3	Describe the rationale for the review in the context of what is already known. Explain why the review questions/objectives lend themselves to a scoping review approach.	3				
Objectives	4	Provide an explicit statement of the questions and objectives being addressed with reference to their key elements (e.g., population or participants, concepts, and context) or other relevant key elements used to conceptualize the review questions and/or objectives.	3				
METHODS							
Protocol and registration	5	Indicate whether a review protocol exists; state if and where it can be accessed (e.g., a Web address); and if available, provide registration information, including the registration number.	n/a				
Eligibility criteria	6	Specify characteristics of the sources of evidence used as eligibility criteria (e.g., years considered, language, and publication status), and provide a rationale.	4, 5				
Information sources*	7	Describe all information sources in the search (e.g., databases with dates of coverage and contact with authors to identify additional sources), as well as the date the most recent search was executed.	4				
Search	8	Present the full electronic search strategy for at least 1 database, including any limits used, such that it could be repeated.	Supplementary appendix 1				
Selection of sources of evidence†	9	State the process for selecting sources of evidence (i.e., screening and eligibility) included in the scoping review.	4,5				
Data charting process‡	10	Describe the methods of charting data from the included sources of evidence (e.g., calibrated forms or forms that have been tested by the team before their use, and whether data charting was done independently or in duplicate) and any processes for obtaining and confirming data from investigators.	5, supplementary appendix 2				
Data items	11	List and define all variables for which data were sought and any assumptions and simplifications made.	5				
Critical appraisal of individual	12	If done, provide a rationale for conducting a critical appraisal of included sources of evidence; describe	n/a

JBI = Joanna Briggs Institute; PRISMA-ScR = Preferred Reporting Items for Systematic reviews and Meta-Analyses

From: Tricco AC, Lillie E, Zarin W, O'Brien KK, Colquhoun H, Levac D, et al. PRISMA Extension for Scoping Reviews (PRISMAScR): Checklist and Explanation. Ann Intern Med. 2018;169:467–473. doi: 10.7326/M18-0850.

^{*} Where sources of evidence (see second footnote) are compiled from, such as bibliographic databases, social media platforms, and Web sites.

[†] A more inclusive/heterogeneous term used to account for the different types of evidence or data sources (e.g., quantitative and/or qualitative research, expert opinion, and policy documents) that may be eligible in a scoping review as opposed to only studies. This is not to be confused with information sources (see first footnote).

[‡] The frameworks by Arksey and O'Malley (6) and Levac and colleagues (7) and the JBI guidance (4, 5) refer to the process of data extraction in a scoping review as data charting.

[§] The process of systematically examining research evidence to assess its validity, results, and relevance before using it to inform a decision. This term is used for items 12 and 19 instead of "risk of bias" (which is more applicable to systematic reviews of interventions) to include and acknowledge the various sources of evidence that may be used in a scoping review (e.g., quantitative and/or qualitative research, expert opinion, and policy document).
