

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email [info.bmjopen@bmj.com](mailto:info.bmjopen@bmj.com)

## PEDAL Protocol: A prospective single arm paired comparison of multiparametric MRI and 18F-DCPFyl PSMA PET/CT to diagnose prostate cancer

Journal:	<i>BMJ Open</i>

38     **Abstract**

39     *Introduction:*

40     Prostate specific membrane antigen positron emission tomography (PSMA-PET) has emerged as

41     valuable imaging to assessing metastatic disease in prostate malignancy. However, there has been

42     limited studies exploring the utility PSMA-PET as primary imaging assessing for index lesions prior to

43     biopsy. The primary objective of this study is to compare the diagnostic accuracy of 18-fluorine

44     PSMA (18F DCFPyL PSMA) PET scans to multiparametric magnetic resonance imaging (mpMRI) to

45     detect primary prostate cancer at prostate biopsy.

46

47     *Methods and Analysis:*

48     The PEDAL trial is a multicentre, prospective, single-arm, paired comparison, non-randomised phase

49     III trial in subjects considered for diagnostic prostate biopsy. Subjects who are eligible for a

50     diagnostic mpMRI prostate will undergo additional same-day 18-F DCFPyL PSMA PET/CT of the chest,

51     abdomen and pelvis. Software co-registration of the mpMRI and PSMA-PET/CT images will be

52     performed. The reporting of the mpMRI prostate, PSMA-PET/CT and PSMA PET/MRI co-registration

53     will be performed blinded.

54     The diagnostic accuracy of PSMA PET/CT alone, and in combination with mpMRI, to detect prostate

55     cancer will be assessed. Histopathology at prostate biopsy will be used as the reference standard.

56     Sample size calculations estimate that 240 subjects will need to be recruited to demonstrate 20%

57     superiority of PSMA-PET/CT.

58     The sensitivity, specificity, positive predictive value and negative predictive value of the combination

59     of mpMRI prostate and PSMA PET/CT compared to targeted and systematic prostate biopsy will be

60     evaluated. It is hypothesised that PSMA PET/CT combined with mpMRI prostate will have improved

61     diagnostic accuracy compared to mpMRI prostate alone for detection of prostate cancer in biopsy-

62     naïve men, resulting in a significant impact on patient management.

63

#### 64 *Ethics and Dissemination:*

65 This study was approved by the independent Human Research Ethics Committee and is a registered  
66 trial (Trial registration number: ACTRN12620000261910). Participant recruitment commenced in  
67 March 2020. Results will be published in peer-reviewed medical journals.

68

#### 69 **Strengths and Limitations**

- 70 • This is a multicentre study.
- 71 • A strength of this study is its prospective nature of the study design controlled by using  
72 patients own biopsy results as comparator, thus limiting confounders.
- 73 • This is an adequately powered study with objective primary and secondary outcome  
74 measures.
- 75 • Potential limitations pertain to generalisability of results given use of DCFPYL tracer for  
76 PSMA-PET/CT. There are currently limited studies directly comparing different PSMA-PET  
77 tracers.

82     **Introduction**

83     Prostate cancer (PCa) is very common, with one in six men being diagnosed before the age of 85

84     years<sup>1</sup>. The age-standardised incidence rate has increased from 80 cases per 100,000 males to 141

85     cases per 100,000 males since 1982, likely driven by the implementation of prostate-specific antigen

86     (PSA) screening. With the growing incidence of disease, prostate imaging has become increasingly

87     important in the diagnostic evaluation of prostate cancer to detect clinically significant prostate

88     cancer (csPCa, Grade group ≥2) and assess tumour burden.

89

90     In Australia, multiparametric magnetic resonance imaging (mpMRI) of the prostate gland has also

91     become available under Australian government funded rebate for diagnostic evaluation of suspected

92     prostate cancer and active surveillance of low-risk prostate cancer with economic analysis

93     suggesting significant savings to the health system<sup>2,3</sup>. mpMRI offers reliable visualisation and

94     characterisation of csPCa compared to the traditional transrectal ultrasound (TRUS), and is seen to

95     have greater sensitivity of detection for lesions greater than 1cm, Gleason score of ≥7 and index

96     lesions compared to satellite lesions, thus enabling better selection of patients for prostate biopsy<sup>4</sup>.

97     In a meta-analysis of 42 studies, the pooled negative predictive value of mpMRI was reported to be

98     90.8 – 97%<sup>5</sup>. mpMRI-targeted prostate biopsy has been reported to detect more csPCa than

99     systematic TRUS-guided biopsy (38% versus 26%)<sup>6</sup>. Nevertheless, mpMRI is not without limitations.

100    Variable imaging quality, interreader variability, low specificity and missed or underestimated

101    tumours remain an issue<sup>7,8</sup>. The PAIREDCAP trial reported 15% of patients with negative mpMRI

102    findings were found to have csPCa on systematic prostate biopsy<sup>9</sup>.

103

104    Along with mpMRI, prostate-specific membrane antigen positron emission tomography (PSMA-PET)

105    is one of the key advancements to emerge in prostate cancer assessment over the last two

106    decades<sup>10,11</sup>. Prostate specific membrane antigen (PSMA) is a type II transmembrane protein that is

107    overexpressed on PCa cell membranes in all but 5 – 10% of cases, showing high specificity and

108 sensitivity relating to tumour aggressiveness and metastatic potential<sup>12,13</sup>. 18F-Choline PET scans  
109 have been shown to improve risk stratification when used in conjunction with mpMRI<sup>14</sup>. This in  
110 conjunction with the prostate specific tracer of PSMA leads to strong support using PSMA-targeted  
111 PET imaging for staging of high-risk disease and biochemical recurrence<sup>15-18</sup>. In the proPSMA trial,  
112 PSMA PET/CT was demonstrated to have 27% greater accuracy than conventional staging  
113 (92% versus 65%) for pelvic or distant metastases, providing superior accuracy with fewer equivocal  
114 results and lower radiation exposure<sup>15</sup>.

115 The use of PSMA PET/CT as a first line diagnostic tool for suspected prostate cancer is under  
116 investigation<sup>19,20</sup>. The PRIMARY study<sup>19</sup> recently reported the additive value of pelvic-only 68Ga-  
117 PSMA PET/CT to a “triaged” mpMRI population to detect csPCa in men with suspicious for prostate  
118 cancer. The trial showed combined PSMA-PET/CT and MRI compared to MRI alone improved the  
119 negative predictive value (91% vs 72%,  $p<0.001$ ) and sensitivity (97% vs. 83%,  $p<0.001$ ). However,  
120 specificity was reduced (40% vs. 53%,  $p=0.01$ ). Several other studies demonstrated similar results of  
121 improved sensitivity<sup>10,21</sup>. Additionally, for equivocal lesions on mpMRI (i.e. PIRADS 3), PSMA-PET/CT  
122 may add to stratification of these lesions, with csPCa was more often detected when any focal PSMA  
123 uptake was detected 3/6 (50%), compared to those with no appreciable PSMA uptake 2/11 (18%)<sup>22</sup>.

124 Finally, PSMA-PET/CT in addition to mpMRI showed increased sensitivity when detecting  
125 extraprostatic extension and seminal vesical invasion<sup>23</sup>, although specificity reduced slightly<sup>23</sup>, as  
126 seen in the PRIMARY trial. Hybrid PET/MRI scanners utilizing the 68Ga-PSMA ligand have also  
127 provided compelling evidence that it may be superior to prostate mpMRI alone to detect csPCa,  
128 however use of these machines will be limited by cost and poor accessibility<sup>24,25</sup>.

129 Given the morbidity and mortality associated with prostate biopsy and prostate cancer treatment,  
130 the potential for improved diagnostic accuracy using PSMA PET/CT to localize prostate cancer in  
131 biopsy-naïve men warrants further investigation. The PEDAL trial is a prospective, single-arm paired

comparison trial that aims to provide high quality evidence regarding the diagnostic accuracy of 18F-DCFPyl-PSMA PET/CT in conjunction with mpMRI prostate for primary diagnosis of prostate cancer.

**Methods and Design:**

*Ethics*

This clinical trial has been approved by the St Vincent’s Hospital, Melbourne Human Research Ethics Committee (HREC 230/19) and is registered on the Australian New Zealand Clinical trials registry (ACTRN12620000261910). It will be conducted in accordance with the International Conference on Harmonisation protocols and Good Clinical Practice. In addition, the trial will be conducted in compliance with all applicable laws and regulatory requirements relevant to the use of new therapeutic agents in Australia and any other participating country. Funding will be acquired through Cyclotek (manufacturer of DCFPYL), General Electrical Healthcare, and philanthropic grants. The trial schema is outlined in Figure 1.

*Patient and public involvement*

No formal patient advisory committee was set up and there was no patient or public involvement in the design and planning of the study. The study was so designed as the mpMRI, PSMA-PET and prostate biopsy procedures used are not novel concepts or techniques, and are widely available in Australia as part of the Medicare system for which consumer and stakeholder comment is sought prior to inclusion of these interventions. Nevertheless, the patients are invited to provide feedback at each point of contact with the healthcare system. In addition, the results are intended for publication in peer reviewed medical journals.

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Ensignement Supérieur (ABES).

155

### 156 *Study design*

157 This is a prospective single arm paired comparison diagnostic phase III trial in patients who are being  
158 considered for diagnostic prostate biopsy to detect prostate cancer. We aim to evaluate the role of  
159 PSMA-PET/CT in those with high clinical suspicion of prostate cancer. The PSMA-PET/CT, by  
160 identifying a suspicious lesion, is likely to impact the decision for prostate biopsy and the target  
161 location. The diagnostic accuracy of the imaging studies will be assessed by comparison of imaging  
162 results to prostate biopsy results.

163

### 164 *Patient screening, eligibility, and enrolment*

165 Patients with features suspicious for PCa based on an abnormal PSA or DRE will be screened by a  
166 urologist for trial eligibility in the study according to the inclusion and exclusion criteria listed below  
167 in Table 1<sup>26</sup>. A target of 240 subjects will be recruited from multiple sites.

**Table 1. Study inclusion and exclusion criteria**

*[Adapted from New Medicare Benefits Scheme (MBS) for mpMRI of the prostate][20]*

**Inclusion criteria**

- Men (≥18 years) with an elevated PSA who are suitable for an eligible MBS mpMRI prostate:  
(MBS items 63541 and 63542) AND who have NOT had recent (≤3 years) prostate biopsy or mpMRI prostate.  
For MBS items 63541 and 63542 (NK) the patient must be suspected of having prostate cancer based on (\*):
  - a) DRE which is suspicious for prostate cancer; or
  - b) in a person aged less than 70 years, at least prostate specific antigen (PSA) tests performed within an interval of 1- 3 months are greater than 3.0 ng/ml, and the free/total PSA ratio is less than 25% or the repeat PSA exceeds 5.5 ng/ml; or
  - c) in a person aged less than 70 years, whose risk of developing prostate cancer based on family history is at least double the average risk, at least two PSA tests performed within an interval of 1- 3 months are greater than 2.0ng/ml, and the free/total PSA ratio is less than 25%; or
  - d) in a person aged 70 years or older, at least two PSA tests performed within an interval of 1- 3 months are greater than 5.5ng/ml and the free/total PSA ratio is less than 25%.*NB: Relevant family history is a first degree relative with prostate cancer or suspected of carrying a BRCA 1, BRCA 2 mutation.*
- Patient has provided written informed consent for participation in trial
- In the opinion of the investigator, willing and able to comply with required study procedures

**Exclusion criteria**

- Known diagnosis of prostate cancer.
- Previous prostate biopsy within 3 years of randomization. A transurethral resection of the prostate performed for primary purpose of alleviating lower urinary tract symptoms is considered acceptable.
- Previous mpMRI prostate within 3 years of randomization.
- History of other active malignancy within the last 3 years, with the exception of non-melanoma skin cancer or melanoma in-situ.
- Any absolute contra-indication to 3T mpMRI prostate, or previous history of total hip joint replacement.
- Significant intercurrent morbidity that, in the judgement of the investigator, would limit compliance with study protocols.

*DRE= digital rectal examination; mpMRI = multiparametric magnetic resonance imaging; PSA= prostate specific antigen*

## 172 *Follow-up*

173 Participants will be followed-up by their referring urologist to discuss results and ongoing  
174 management of either PSA surveillance, active surveillance, radical treatment or non-curative  
175 treatment.

## 177 **Funding**

178 Subjects will be informed of the costs of participation as part of the informed consent. For those  
179 eligible, the mpMRI will be funded through the Australian Government Department of Health  
180 Medicare Benefits Scheme (i.e. free of charge to the patient). The PSMA PET/CT will be funded  
181 through the clinical trial. The prostate biopsy will be funded as standard practice through the  
182 Medicare Benefits Scheme, private health insurance and subject. Subjects will not be paid for their  
183 participation and no participating clinical or researcher will be paid outside of their normal salary.

## 185 **Diagnostic Imaging Procedures**

186 All participants will undergo both the PSMA-PET/CT and mpMRI within four weeks of enrolment into  
187 this study and both scans performed on the same day to minimise disruption to participants'  
188 personal schedules. To standardize parameters of acquisition and image quality, these will be  
189 performed at an approved study centre.

## 191 *Multiparametric MRI*

192 All subjects will undergo 3-Tesla mpMRI prostate according to standard protocols (Appendix 1). The  
193 images will be reported by a single experienced Radiologist using the Prostate Imaging–Reporting  
194 and Data System (PI-RADS) version 2.1 on a scale of 1 to 5 (Appendix 2). Any suspicious intraprostatic

195 lesion described as PI-RADS 3 or greater will be considered a positive lesion with a targeted prostate  
196 biopsy recommended. The presence of extracapsular extension, seminal vesicle invasion,  
197 locoregional disease and subjective likelihood of csPCa will be recorded. The initial report of the  
198 mpMRI prostate will be blinded to the PSMA-PET/CT result.

199

200 *PSMA-PET/CT*

201 All participants will undergo PSMA-PET/CT imaging with 18F-DCFPyL according to standard protocol  
202 (Appendix 3) at the participating site, on the same day as the mpMRI. The 18F-DCFPyL radiotracer  
203 will be produced in Australia and New Zealand by Cyclotek Pty Ltd, who will provide the local site  
204 with a Quality Control Release notification form. A single, intravenous bolus dose of 18F-DCFPyL  
205 PSMA (250MBq +/-50 MBq) will be administered with an uptake time of 120 minutes post 18F-  
206 DCFPyL injection. 18F-PSMA PET with CT chest, abdomen and pelvis will be performed for anatomic  
207 localisation and attenuation correction

208 PSMA-PET/CT images will be reported at a per-patient and per-lesion level by an experienced reader  
209 at each site. The initial report of PSMA-PET/CT will be blinded to the mpMRI prostate result. To  
210 standardise lesion imaging reporting, the intraprostatic lesions will be described according to the  
211 sector map specified in PI-RADS version 2.1 for mpMRI prostate. The PSMA intensity score  
212 (SUVmax), focality and ratio to background will be assessed. The reader will report disease location  
213 and extent, as well as assign a subjective likelihood for the presence of csPCa. All lesions with  
214 SUVmax scores of 4.0 or higher are deemed appropriate for targeted biopsy. While results of the  
215 PRIMARY trial were disseminated after our protocol was designed, it also uses a SUVmax of 4.0 as at  
216 this stage the sensitivity for csPCa was 92%<sup>19</sup>. This may be adjusted following quantitative analysis of  
217 thresholds, (liver and background prostate in particular), for the presence of malignancy, although  
218 the PRIMARY trial would suggest that adjustments will not be required<sup>19</sup>.

Enseignement Supérieur (ABES)

219

## 220 *Co-registration of the PSMA-PET/CT with mpMRI prostate*

221 After both diagnostic imaging arms have been independently reported, co-registration of the two  
 222 modalities will be performed using the GE Advantage Workstation® (General Electric, Boston,  
 223 Massachusetts, United States) software. Reporting of co-registered PSMA-PET/CT with mpMRI  
 224 images will be performed by an experienced dual-trained radiologist with PET accreditation and  
 225 experience of reporting prostate mpMRI. A synoptic report will describe lesions seen on the mpMRI  
 226 alone, PSMA-PET/CT alone, followed by the result of the co-registration process to determine  
 227 concordance between 18F-DCFPyL PSMA-PET and mpMRI and the reader's subjective likelihood of  
 228 the presence of csPCa will be reported. Lesions will be numbered to enable accurate cataloguing at  
 229 time of prostate biopsy, and visually represented on the PI-RADS version 2.1 prostate map.

230

## 231 **Prostate Biopsy**

### 232 *Prostate biopsy procedure*

233 The referring urologist will have access to reports and images for both diagnostic imaging modalities  
 234 and PSMA-PET/MRI co-registration results in order to make a clinical decision regarding prostate  
 235 biopsy. Subjects with any positive and/or equivocal findings in either diagnostic imaging arm are  
 236 recommended to undergo a targeted biopsy of all lesions and a systematic biopsy for  
 237 histopathological analysis. Targeting is accomplished via cognitive fusion at time of biopsy. The study  
 238 recommends a standardised transperineal ultrasound guided template biopsy format performed  
 239 under general anaesthesia. A minimum of four cores of any targeted lesion and minimum 24  
 240 systematic cores to be taken. Subjects with no abnormalities on mpMRI and PSMA PET/CT are  
 241 recommended to have a systematic biopsy (24 cores). All biopsies are performed by surgeons

242 already trained in and practicing the transperineal biopsy route, thus minimising variability and  
243 possible confounders.

244

245 *Histopathology*

246 Biopsy specimens will be labelled based on location and whether obtained through targeted or  
247 systematic prostate biopsy. Reporting of the prostate biopsy will be performed by genito-urinary  
248 histopathologists at each site using standardized proformas, detailing the number of cores taken,  
249 location (including the index lesion), histological subtype, and International Society of Urological  
250 Pathology (ISUP) grade group, number of positive cores per site, percentage and longest length of  
251 cancer in one core and perineural invasion<sup>27</sup>.

253 **Study assessment**

254 *Study objective and endpoints*

255 The endpoints of this study are summarised in Table 2. The primary objective is to assess for  
256 diagnostic superiority of PSMA-PET/CT in combination with mpMRI in detection of lesions with any  
257 ISUP grade prostate cancer. Specifically, cancer detection rates, sensitivity, specificity, negative  
258 predictive values, positive predictive values and AUC are explored. The secondary outcomes involve  
259 detection of csPCa.

Enseignement Supérieur (ABES)

**Table 2. PEDAL Study endpoints****Primary endpoint**

- Comparison of diagnostic accuracy of mpMRI prostate to PSMA-PET/CT alone and in combination with mpMR in the detection of prostate cancer (any ISUP) per patient and per lesion.

**Secondary endpoints**

- Detection of clinically significant (ISUP Grade Group  $\geq 2$ ) primary prostate cancer at prostate biopsy
- Detection of radiologically significant lesions in the prostate at PSMA-PET/CT and MRI co-registration.
- Detection of radiological evidence of metastatic lesions on PSMA-PET/CT and/or mpMRI Prostate.
- Number of adverse events reported during and post-administration of radiotracer for PSMA PET/CT.

*ISUP= International Society of urological Pathology; mpMRI= multiparametric magnetic resonance imaging; PSMA=prostate specific membrane antigen; PET/CT=positron emission tomography / computed tomography,*

**Sample size and Power Calculation**

The trial will proceed to recruit to an ideally powered sample size of 240 subjects to achieve a power of 0.80. Sample size calculations were based on the primary endpoint of detection of all ISUP grade prostate cancer detection. Area under the receiver operator characteristic (ROC) curve (the AUC), sensitivity and specificity for mpMRI and PSMA-PET/CT are 0.84, 0.603 and 0.89<sup>28</sup>, and 0.91, 0.88 and 0.93<sup>29</sup> respectively. The following assumptions were made for sample size calculations: 50% of men who undergo prostate biopsy will be diagnosed with prostate cancer, , the proportion of cases (PSMA PET/CT as opposed to mpMRI) is 20% higher, the absolute margin of improvement is 7% (0.35 to 0.42) to declare PSMA-PET/CT is superior, the estimated correlation between the two tests is 80% and a two-sided type I error of 5%. In addition, this sample size makes allowance for a dropout rate of 10%.

275

276 *Blinding*

277 Blinding occurs at the level of the clinician reviewing the imaging and biopsy specimens. Separate  
278 clinicians review the mpMRI, PSMA-PET/CT and co-registered PMSA-PET/CT and mpMRI images,  
279 with each clinician blinded to the results of the other two imaging assessment modalities. The  
280 uropathologist will receive tissue samples labelled as a systematic or targeted biopsy and its  
281 position, however is blinded to the results of PI-RADS score or PSMA-PET/CT positivity.

282

283 *Results and Outcomes*

284 Summary tables will be prepared giving numbers of participants by arm, disease assessment  
285 compliance, eligibility infringements and losses to follow-up. Baseline characteristics by treatment  
286 arm will be summarized in frequency tables by the use of descriptive statistics for variables. Ninety-  
287 five percent confidence intervals (95% CI) for differences between arms of all important endpoints  
288 will be calculated, and p-values will be two-sided. Exact tests will be performed with binary outcome  
289 data.

290

291 *Diagnostic Accuracy*

292 To determine diagnostic accuracy of PSMA PET/CT compared to mpMRI prostate in the detection of  
293 csPCa, findings of imaging will be compared to prostate biopsy histopathology to determine  
294 presence or absence of cancer. Clinically significant prostate cancer at prostate biopsy is defined as  
295 ISUP Grade Group  $\geq 2$ . For the primary objective, positivity will be defined by histological  
296 confirmation of cancer at prostate biopsy.

297

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.  
Enseignement Supérieur (ABES)

Accuracy of each diagnostic imaging arm will be assessed by the AUC. mpMRI accuracy will be compared to PSMA PET/CT alone, and in combination with mpMRI. Point estimates of the sensitivity and specificity of each modality alone will be determined, and approximations to their distributions will be estimated using the normal approximation to the binomial distribution. Using independence of the sensitivity and specificity, the AUC will be calculated as the mean of the estimated sensitivity and specificity, and its variance as the sum of the variances of the sensitivity and specificity. Equivocal lesions will be considered negative for clinical purposes, however these lesions will be targeted during biopsy and a sensitivity analysis will be performed in which lesions rated as equivocal will be considered positive for malignancy. The difference between the AUCs will be used to characterise the true underlying difference between AUC's of the two modalities and to apply a hypothesis test for the existence of a clinically important difference between them (the null hypothesis will be a 7% difference).

310

### 311 *Risks of PSMA-PET/CT*

Several preclinical and clinical studies have shown the safety of 18F-PSMA. The critical dose-organs are the kidneys (0.0945 mSv/MBq) and urinary bladder (0.085 mSv/MBq) and were calculated from human biodistribution data using OLINDA/EXM (Organ Level Internal Dose Assessment/Exponential Modelling) software. Based on the FDA, a single-organ dose of 0.05 Sv is allowable. This corresponds to an activity of 400 MBq (10.8 mCi) of 18F-PSMA for a 70-100 kg male subject with a prostate cancer, well above the doses used in this study. Accordingly, the effective dose expected to the whole body is 0.0066 Sv, which is below the 0.03 Sv upper limit recommended by the Food and Drug Administration (FDA).

No adverse effects due to intravenous administration of 18 F-PSMA for imaging have been reported in the published literature. There are no known contraindications for 18F-PSMA. Overall, 18F-PSMA PET scan may be used in clinical research with no risk to subjects with PCa. Acute adverse events, defined as those experienced by the subject at the time of radiotracer administration and during the two hours following injection will be recorded. Any toxicity will be graded by NCI Common Terminology Criteria for Adverse Events (CTCAE) version 5.0<sup>30</sup>.

**Discussion**

The drive to accurately detect intraprostatic and extraprostatic disease at the time of prostate cancer diagnosis has led to the intense interest in PSMA-PET/CT as an adjunct to mpMRI prostate. PSMA PET/CT has shown to be highly useful in the setting of high-risk disease and biochemical failure post-radical treatment<sup>31,32</sup>, however its utility as a diagnostic tool for prostate cancer evaluation until recently<sup>19</sup>, there has had minimal high-quality prospective data. Our hypothesis is that PSMA-PET/CT will be superior in diagnostic accuracy to mpMRI prostate at identifying cancer within the prostate. As mpMRI prostate is established in its ability to successfully identify prostate cancer, this is a high standard to achieve. Even if PSMA-PET/CT does not supersede mpMRI prostate in diagnostic accuracy, establishing comparable diagnostic accuracy may result in a viable alternative for men who have contraindications to mpMRI. The trial may also demonstrate (i) a synergistic effect in cancer diagnosis by the combination of the two imaging techniques, (ii) a benefit for PSMA-PET/CT in men with equivocal mpMRI prostate findings; (iii) benefit for men with concerning clinical features but negative/equivocal mpMRI prostate; and (iv) provide an all-encompassing diagnostic and staging scan for men who have high risk features for metastatic disease at diagnosis. Unlike the PRIMARY trial, our PSMA-PET/CT

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.  
Enseignement Supérieur (ABES)

protocol encompasses chest, abdomen and pelvis, so will be able to add valuable information to this outcome.

Proprietary software from the GE Advantage® Workstation will perform co-registration between mpMRI prostate and PSMA-PET/CT images will be utilised in this trial. Co-registration has potential to improve targeting of prostate biopsy techniques, and help provide an alternative to expensive, difficult to access hybrid PET/MRI machines.

After diagnostic accuracy of PSMA-PET/CT is established, its potential for significant economic impact as a diagnostic test can be thoroughly investigated. Reductions in prostate biopsy, efficiencies in consolidation of diagnostic and staging imaging tests, and using software co-registration as an alternative to hybrid PET/MRI all represent potential economic benefits to our health system.

The PEDAL trial commenced in March 2020, and although recruitment has been delayed due to Covid 19 related adjustments in health care delivery the current aim is to complete recruitment in 36 months. This innovative study will add valuable evidence to demonstrate the diagnostic accuracy of PSMA-PET/CT. It has potential to significantly impact how prostate cancer is diagnosed.

#### **Funding statement**

This clinical trial is supported by Cyclotek (Aust) Pty Ltd and their key partners, the Australian Government as part of its CRC Projects Program, General Electrical Healthcare, Macquarie University and the EJ Whitten Prostate Cancer Research Centre at Epworth Healthcare. We are also grateful for philanthropic donations from Reese Limited, the Pitcher and Cicutto families via the St Vincent's Foundation.

## Appendix 1: Multiparametric Magnetic Resonance Imaging Protocol

### IMAGING ACQUISITION:

MRI prostate imaging is acquired as per international guidelines specified by Prostate Imaging-Reporting and Data System, version 2.1 (PIRADS V2.1).

A multi-parametric MRI scan will be performed according to the following technical protocol, consistent with the highest standards of prostate MRI after appropriate bowel preparation (suggest Microlax suppository morning of diagnostic imaging) and buscopan or glucagon injection (where not contraindicated):

- 3-Tesla magnet field strength
- 32-channel cardiac coil, anteriorly and spinal coil posteriorly
- T2 sequences to show pathology, aid localisation of the lesion, and to fuse with ultrasound for those Urologists using co-registration biopsy method.
  - High resolution T2 FSE in 3 planes: axial, coronal and sagittal
  - 3D T2 sequence

Diffusion-Weighted Imaging (DWI) with software derived Apparent Diffusion Co-efficient (ADC) quantitative analysis maps, and multiple b-values (acquired b50, acquired b1400, calculated b2000);

Dynamic Contrast Enhanced imaging (DCE) 3D imaging, with IV gadolinium DTPA bolus determined by body weight, at 2.5ml/second followed by T1 DCE TRICKS (Time-Resolved Imaging of Contrast KineticS).

Analysis of DCEI according to PI-RADS DCEI analytic guidelines using PROCAD software

- No use of Endo-rectal coils or MR Spectroscopy as per current guidelines
- Approximate scan time 30 to 40 minutes

### CONTRAINDICATIONS TO MRI

24 Patient with any contraindication to MRI will not undergo MRI. This includes, but not restricted, to

25 pacemaker or other electronic implants, total hip joint replacement, known metal in the orbit, MR

26 incompatible surgical or cerebral aneurysm clips, shrapnel, non-removable body piercings.

27 **REPORTING OF MPMRI PROSTATE**

28 The mpMRI will be reported by experienced subspecialist Radiologists according to the Prostate

29 Imaging-Reporting and Data System, version 2.1, with each lesion categorised on a scale from 1 to 5.

30 **OPTIMIZATION OF CO-REGISTRATION BETWEEN MPMRI PROSTATE AND PSMA-PET/CT**

31 To enable better co-registration of mpMRI to PSMA-PET/CT:

- 32 • option to use of suppositories to help eliminate gas/faeces from rectum
- 33 • ensure flat pelvis
- 34 • Use of structured knee bolster and strapping of feet to aid pelvic alignment

**Appendix 3: 18F-DCFPyL PSMA administration and PET/CT Imaging Protocol**

**RADIOPHARMACEUTICAL**

18F DCFPyL will be produced at Cyclotek (Aust) Pty Ltd under GMP Licence Number MI-12092005-LI-000904-2 and (parametric) release after certain quality control tests are performed and transported to the imaging site under regulatory criteria for dangerous goods. Cyclotek will provide the imaging site with a Quality Control Release notification form. Patients will complete the radiopharmaceutical consent form at their local site prior to injection.

**18F-DCFPYL PSMA INJECTION DOSING AND ADMINISTRATION**

Patients will be administered a single, intravenous 250MBq bolus dose of 18F-DCFPyL PSMA (acceptable: 200-300MBq depending on patient weight and activity provided on day of scan). The administered activity of 18F-DCFPyL PSMA is approximately 3MBq per kilogram body weight up to 350 maximum dose.

**18F-PSR PET/CT imaging protocol for initial diagnosis/staging of Prostate Ca Imaging Protocol**

**Patient Preparation:**

- No fasting required. (\*Must be well hydrated, approximately 1-2 litres of plain water in the 2 hours before appointment.)
- The activity is administered intravenously through a cannula either utilising the automatic injector and a 100ml Saline bag or via hand injection through the cannula utilising the 5ml syringe shield and 2x10mls saline flushes.
- The dose pre and post syringe activities and times must be recorded to work out the exact administered activity for the injection time.
- Uptake Time: 120 minutes post 18F-DCFPyL injection. The patient is free to leave the department if they wish during this waiting time.

- 64 • Patient to void before the scan

65 **SCANNER**

66 Patients will be imaged on a GE Discovery 690 or 710 PET/CT (General Electric Medical Systems,  
67 Milwaukee, WI) combining a 64 slice multidetector CT scanner with a dedicated, full ring PET scanner  
68 with lutetium-based crystals.

69 **Scan:**

70 *Scan range:* Mid/Upper thighs to Lung Apices. Patient position supine, arms up and feet first to  
71 ensure bladder is in its emptiest state. CT scan acquired using a low-dose protocol (120/140 kVp and  
72 automatic exposure control ('Smart mA', max 200mA). Low-dose attenuation correction CT images  
73 were acquired and reconstructed to a 3.75mm slice thickness with an increment of 3.27mm using  
74 iterative reconstruction (50% ASiR). PET images were acquired at 3.5min/bed through the pelvis and  
75 3.0min/bed to the lung apices. PET images were reconstructed from time of flight emission data  
76 using VUE Point FX and Q-Clear™ iterative technique with  $\beta$  value of 400. Q-Clear™ is a fully  
77 convergent reconstruction method which incorporates point spread function corrections, scatter  
78 correction and ULD-CT attenuation corrections. Sharp IR function was applied with no Z-axis filter.  
79 PET images were reconstructed on a 256 matrix.

## Abstract

### *Introduction:*

Prostate specific membrane antigen positron emission tomography (PSMA-PET) has emerged as valuable imaging to assessing metastatic disease in prostate malignancy. However, there has been limited studies exploring the utility PSMA-PET as primary imaging assessing for index lesions prior to biopsy. The primary objective of this study is to compare the diagnostic accuracy of 18-fluorine PSMA (18F DCFPyL PSMA) PET scans to multiparametric magnetic resonance imaging (mpMRI) to detect primary prostate cancer at prostate biopsy.

### *Methods and Analysis:*

The PEDAL trial is a multicentre, prospective, single-arm, paired comparison, non-randomised phase III trial in subjects considered for diagnostic prostate biopsy. Subjects who are eligible for a diagnostic mpMRI prostate will undergo additional same-day 18-F DCFPyL PSMA PET/CT of the chest, abdomen and pelvis. Software co-registration of the mpMRI and PSMA-PET/CT images will be performed. The reporting of the mpMRI prostate, PSMA-PET/CT and PSMA PET/MRI co-registration will be performed blinded.

The diagnostic accuracy of PSMA PET/CT alone, and in combination with mpMRI, to detect prostate cancer will be assessed. Histopathology at prostate biopsy will be used as the reference standard.

Sample size calculations estimate that 240 subjects will need to be recruited to demonstrate 20% superiority of PSMA-PET/CT.

The sensitivity, specificity, positive predictive value and negative predictive value of the combination of mpMRI prostate and PSMA PET/CT compared to targeted and systematic prostate biopsy will be evaluated. It is hypothesised that PSMA PET/CT combined with mpMRI prostate will have improved diagnostic accuracy compared to mpMRI prostate alone for detection of prostate cancer in biopsy-naïve men, resulting in a significant impact on patient management.

*Ethics and Dissemination:*

This study was approved by the independent Human Research Ethics Committee and is a registered trial (Trial registration number: ACTRN12620000261910). Results will be published in peer-reviewed medical journals with eligible investigators will significantly contribute.

**Strengths and Limitations**

- This is a multicentre study.
- A strength of this study is its prospective nature of the study design controlled by using patients own biopsy results as comparator, thus limiting confounders.
- This is an adequately powered study with objective primary and secondary outcome measures.
- Potential limitations pertain to generalisability of results given use of DCFPYL tracer for PSMA-PET/CT. There are currently limited studies directly comparing different PSMA-PET tracers.

## Introduction

Prostate cancer (PCa) is very common, with one in six men being diagnosed before the age of 85 years[1]. The age-standardised incidence rate has increased from 80 cases per 100,000 males to 141 cases per 100,000 males since 1982, likely driven by the implementation of prostate-specific antigen (PSA) screening. With the growing incidence of disease, prostate imaging and biomarkers[2, 3] has become increasingly important in the diagnostic evaluation of prostate cancer to detect clinically significant prostate cancer (csPCa, Grade group  $\geq 2$ ) and assess tumour burden.

In Australia, multiparametric magnetic resonance imaging (mpMRI) of the prostate gland has also become available under Australian government funded rebate for diagnostic evaluation of suspected prostate cancer and active surveillance of low-risk prostate cancer with economic analysis suggesting significant savings to the health system[4, 5]. mpMRI offers reliable visualisation and characterisation of csPCa compared to the traditional transrectal ultrasound (TRUS), and is seen to have greater sensitivity of detection for lesions greater than 1cm, Gleason score of  $\geq 7$  and index lesions compared to satellite lesions, thus enabling better selection of patients for prostate biopsy[6]. In a meta-analysis of 42 studies, the pooled negative predictive value of mpMRI was reported to be 90.8 – 97%[7]. mpMRI-targeted prostate biopsy has been reported to detect more csPCa than systematic TRUS-guided biopsy (38% versus 26%)[8]. Nevertheless, mpMRI is not without limitations. Variable imaging quality, interreader variability, low specificity and missed or underestimated tumours remain an issue[9, 10]. The PAIREDCAP trial reported 15% of patients with negative mpMRI findings were found to have csPCa on systematic prostate biopsy[11].

Along with mpMRI, prostate-specific membrane antigen positron emission tomography (PSMA-PET) is one of the key advancements to emerge in prostate cancer assessment over the last two decades[12, 13]. Prostate specific membrane antigen (PSMA) is a type II transmembrane protein that is overexpressed on PCa cell membranes in all but 5 – 10% of cases, showing high specificity and

sensitivity relating to tumour aggressiveness and metastatic potential[14, 15]. 18F-Choline PET scans have been shown to improve risk stratification when used in conjunction with mpMRI[16] . This in conjunction with the prostate specific tracer of PSMA leads to strong support using PSMA-targeted PET imaging for staging of high-risk disease and biochemical recurrence [17-20]. In the proPSMA trial, PSMA PET/CT was demonstrated to have 27% greater accuracy than conventional staging (92% versus 65%) for pelvic or distant metastases, providing superior accuracy with fewer equivocal results and lower radiation exposure[17]. Moreover, recent evidence demonstrate that Ga-PSMA-11 intensity on PET/CT imaging is associated with Gleason score, and is more intense in those patients who underwent upgrading of their Gleason score at biopsy to Gleason score at radical prostatectomy[21], and could develop to be a new biomarker for prognosis in prostate cancer.

The use of PSMA PET/CT as a first line diagnostic tool for suspected prostate cancer is under investigation[22, 23]. The PRIMARY study[22] recently reported the additive value of pelvic-only 68Ga-PSMA PET/CT to a “triaged” mpMRI population to detect csPCa in men with suspicious for prostate cancer. The trial showed combined PSMA-PET/CT and MRI compared to MRI alone improved the negative predictive value (91% vs 72%,  $p<0.001$ ) and sensitivity (97% vs. 83%,  $p<0.001$ ). However, specificity was reduced (40% vs. 53%,  $p=0.01$ ). Several other studies demonstrated similar results of improved sensitivity[12, 24]. Additionally, for equivocal lesions on mpMRI (i.e. PIRADS 3), PSMA-PET/CT may add to stratification of these lesions, with csPCa was more often detected when any focal PSMA uptake was detected 3/6 (50%), compared to those with no appreciable PSMA uptake 2/11 (18%) [25]. Finally, PSMA-PET/CT in addition to mpMRI showed increased sensitivity when detecting extraprostatic extension and seminal vesical invasion[26], although specificity reduced slightly[26], as seen in the PRIMARY trial. Hybrid PET/MRI scanners utilizing the 68Ga-PSMA ligand have also provided compelling evidence that it may be superior to

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Ensignement Supérieur (ABES).

prostate mpMRI alone to detect csPCa, however use of these machines will be limited by cost and poor accessibility[27, 28].

Given the morbidity and mortality associated with prostate biopsy and prostate cancer treatment, the potential for improved diagnostic accuracy using PSMA PET/CT to localize prostate cancer in biopsy-naïve men warrants further investigation. The PEDAL trial is a prospective, single-arm paired comparison trial that aims to provide high quality evidence regarding the diagnostic accuracy of 18F-DCFPyl-PSMA PET/CT in conjunction with mpMRI prostate for primary diagnosis of prostate cancer.

## Methods and Design:

### *Ethics*

This clinical trial has been approved by the St Vincent's Hospital, Melbourne Human Research Ethics Committee (HREC 230/19) and is registered on the Australian New Zealand Clinical trials registry (ACTRN12620000261910). The current protocol is version 3, dated June 2019. It will be conducted in accordance with the International Conference on Harmonisation protocols and Good Clinical Practice. In addition, the trial will be conducted in compliance with all applicable laws and regulatory requirements relevant to the use of new therapeutic agents in Australia and any other participating country. Funding will be acquired through Cyclotek (manufacturer of DCFPYL), General Electrical Healthcare, and philanthropic grants. These parties will not be involved in study design; data processing and interpretation; writing of the report; and the decision to submit the report for publication.

The trial schema is outlined in Figure 1.

*Patient and public involvement*

No formal patient advisory committee was set up and there was no patient or public involvement in the design and planning of the study. The study was so designed as the mpMRI, PSMA-PET and prostate biopsy procedures used are not novel concepts or techniques, and are widely available in Australia as part of the Medicare system for which consumer and stakeholder comment is sought prior to inclusion of these interventions. Nevertheless, the patients are invited to provide feedback at each point of contact with the healthcare system. In addition, the results are intended for publication in peer reviewed medical journals.

*Study design*

This is a prospective single arm paired comparison diagnostic phase III trial in patients who are being considered for diagnostic prostate biopsy to detect prostate cancer. We aim to evaluate the role of PSMA-PET/CT in those with high clinical suspicion of prostate cancer. The PSMA-PET/CT, by identifying a suspicious lesion, is likely to impact the decision for prostate biopsy and the target location. The diagnostic accuracy of the imaging studies will be assessed by comparison of imaging results to prostate biopsy results. Any modifications and updates to study protocol will be communicated to the relevant parties via e-mail.

*Patient screening, eligibility, and enrolment*

Patients with features suspicious for PCa based on an abnormal PSA or DRE will be screened by a urologist for trial eligibility in the study according to the inclusion and exclusion criteria listed below in Table 1[29], and will be consented by the urologist (including for any ancillary studies). Where a substitute decision make is required, the legal next of kin or the power of attorney may consent in

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Enseignement Supérieur (ABES).

the patient's stead. A target of 240 subjects will be recruited from multiple sites. Aside from the addition of PSMA PET/CT, all patients will follow routine care for prostate cancer and there are no specific interventions that are prohibited or permitted.

For peer review only

**Table 1. Study inclusion and exclusion criteria**

*[Adapted from New Medicare Benefits Scheme (MBS) for mpMRI of the prostate][20]*

**Inclusion criteria**

- Men (≥18 years) with an elevated PSA who are suitable for an eligible MBS mpMRI prostate:  
(MBS items 63541 and 63542) AND who have NOT had recent (≤3 years) prostate biopsy or mpMRI prostate.  
For MBS items 63541 and 63542 (NK) the patient must be suspected of having prostate cancer based on (\*):
  - a) DRE which is suspicious for prostate cancer; or
  - b) in a person aged less than 70 years, at least prostate specific antigen (PSA) tests performed within an interval of 1- 3 months are greater than 3.0 ng/ml, and the free/total PSA ratio is less than 25% or the repeat PSA exceeds 5.5 ng/ml; or
  - c) in a person aged less than 70 years, whose risk of developing prostate cancer based on family history is at least double the average risk, at least two PSA tests performed within an interval of 1- 3 months are greater than 2.0ng/ml, and the free/total PSA ratio is less than 25%; or
  - d) in a person aged 70 years or older, at least two PSA tests performed within an interval of 1- 3 months are greater than 5.5ng/ml and the free/total PSA ratio is less than 25%.*NB: Relevant family history is a first degree relative with prostate cancer or suspected of carrying a BRCA 1, BRCA 2 mutation.*
- Patient has provided written informed consent for participation in trial
- In the opinion of the investigator, willing and able to comply with required study procedures

**Exclusion criteria**

- Known diagnosis of prostate cancer.
- Previous prostate biopsy within 3 years of recruitment. A transurethral resection of the prostate performed for primary purpose of alleviating lower urinary tract symptoms is considered acceptable.
- Previous mpMRI prostate within 3 years of recruitment.
- History of other active malignancy within the last 3 years, with the exception of non-melanoma skin cancer or melanoma in-situ.
- Any absolute contra-indication to 3T mpMRI prostate, or previous history of total hip joint replacement.
- Significant intercurrent morbidity that, in the judgement of the investigator, would limit compliance with study protocols.

*DRE= digital rectal examination; mpMRI = multiparametric magnetic resonance imaging; PSA= prostate specific antigen*

### *Follow-up*

Participants will be followed-up by their referring urologist to discuss results and ongoing management of either PSA surveillance, active surveillance, radical treatment or non-curative treatment. Patient retention and follow-up is anticipated to be complete as the study patients require further testing (eg. Biopsy) to complete management of their prostate cancer.

### **Funding**

Subjects will be informed of the costs of participation as part of the informed consent. For those eligible, the mpMRI will be funded through the Australian Government Department of Health Medicare Benefits Scheme (i.e. free of charge to the patient). The PSMA PET/CT will be funded through the clinical trial. The prostate biopsy will be funded as standard practice through the Medicare Benefits Scheme, private health insurance and subject. Subjects will not be paid for their participation and no participating clinical or researcher will be paid outside of their normal salary.

### **Diagnostic Imaging Procedures**

All participants will undergo both the PSMA-PET/CT and mpMRI within four weeks of enrolment into this study and both scans performed on the same day to minimise disruption to participants' personal schedules. To standardize parameters of acquisition and image quality, these will be performed at an approved study centre.

### *Multiparametric MRI*

All subjects will undergo 3-Tesla mpMRI prostate according to standard protocols (Appendix 1). The images will be reported by a single experienced Radiologist using the Prostate Imaging–Reporting

and Data System (PI-RADS) version 2.1 on a scale of 1 to 5 (Appendix 2). Any suspicious intraprostatic lesion described as PI-RADS 3 or greater will be considered a positive lesion with a targeted prostate biopsy recommended. The presence of extracapsular extension, seminal vesicle invasion, locoregional disease and subjective likelihood of csPCa will be recorded. The initial report of the mpMRI prostate will be blinded to the PSMA-PET/CT result.

*PSMA-PET/CT*

All participants will undergo PSMA-PET/CT imaging with 18F-DCFPyL according to standard protocol (Appendix 3) at the participating site, on the same day as the mpMRI. The 18F-DCFPyL radiotracer will be produced in Australia and New Zealand by Cyclotek Pty Ltd, who will provide the local site with a Quality Control Release notification form. A single, intravenous bolus dose of 18F-DCFPyL PSMA (250MBq +/-50 MBq) will be administered with an uptake time of 120 minutes post 18F-DCFPyL injection. 18F-PSMA PET with CT chest, abdomen and pelvis will be performed for anatomic localisation and attenuation correction

PSMA-PET/CT images will be reported at a per-patient and per-lesion level by an experienced reader at each site. The initial report of PSMA-PET/CT will be blinded to the mpMRI prostate result. To standardise lesion imaging reporting, the intraprostatic lesions will be described according to the sector map specified in PI-RADS version 2.1 for mpMRI prostate. The PSMA intensity score (SUVmax), focality and ratio to background will be assessed. The reader will report disease location and extent, as well as assign a subjective likelihood for the presence of csPCa. All lesions with SUVmax scores of 4.0 or higher are deemed appropriate for targeted biopsy. While results of the PRIMARY trial were disseminated after our protocol was designed, it also uses a SUVmax of 4.0 as at this stage the sensitivity for csPCa was 92%[22]. This may be adjusted following quantitative analysis

of thresholds, (liver and background prostate in particular), for the presence of malignancy, although the PRIMARY trial would suggest that adjustments will not be required[22].

### *Co-registration of the PSMA-PET/CT with mpMRI prostate*

After both diagnostic imaging arms have been independently reported, co-registration of the two modalities will be performed using the GE Advantage Workstation® (General Electric, Boston, Massachusetts, United States) software. Reporting of co-registered PSMA-PET/CT with mpMRI images will be performed by an experienced dual-trained radiologist with PET accreditation and experience of reporting prostate mpMRI. A synoptic report will describe lesions seen on the mpMRI alone, PSMA-PET/CT alone, followed by the result of the co-registration process to determine concordance between 18F-DCFPyL PSMA-PET and mpMRI and the reader's subjective likelihood of the presence of csPCa will be reported. Lesions will be numbered to enable accurate cataloguing at time of prostate biopsy, and visually represented on the PI-RADS version 2.1 prostate map.

## **Prostate Biopsy**

### *Prostate biopsy procedure*

The referring urologist will have access to reports and images for both diagnostic imaging modalities and PSMA-PET/MRI co-registration results in order to make a clinical decision regarding prostate biopsy. Subjects with any positive and/or equivocal findings in either diagnostic imaging arm are recommended to undergo a targeted biopsy of all lesions and a systematic biopsy for histopathological analysis. Targeting is accomplished via cognitive fusion at time of biopsy. The study recommends a standardised transperineal ultrasound guided template biopsy format performed under general anaesthesia. A minimum of four cores of any targeted lesion and minimum 24 systematic cores to be taken. Subjects with no abnormalities on mpMRI and PSMA PET/CT are

recommended to have a systematic biopsy (24 cores). All biopsies are performed by surgeons already trained in and practicing the transperineal biopsy route, thus minimising variability and possible confounders.

*Histopathology*

Biopsy specimens will be labelled based on location and whether obtained through targeted or systematic prostate biopsy. Reporting of the prostate biopsy will be performed by genito-urinary histopathologists at each site using standardized proformas, detailing the number of cores taken, location (including the index lesion), histological subtype, and International Society of Urological Pathology (ISUP) grade group, number of positive cores per site, percentage and longest length of cancer in one core and perineural invasion[30].

**Study assessment**

*Study objective and endpoints*

The endpoints of this study are summarised in Table 2. The primary objective is to assess for diagnostic superiority of PSMA-PET/CT in combination with mpMRI in detection of lesions with any ISUP grade prostate cancer. Specifically, cancer detection rates, sensitivity, specificity, negative predictive values, positive predictive values and AUC are explored. The secondary outcomes involve detection of csPCa as well as a cost evaluation using a decision curve analysis.

**Table 2. PEDAL Study endpoints****Primary endpoint**

- Comparison of diagnostic accuracy of mpMRI prostate to PSMA-PET/CT alone and in combination with mpMR in the detection of prostate cancer (any ISUP) per patient and per lesion.

**Secondary endpoints**

- Detection of clinically significant (ISUP Grade Group  $\geq 2$ ) primary prostate cancer at prostate biopsy
- Detection of radiologically significant lesions in the prostate at PSMA-PET/CT and MRI co-registration.
- Detection of radiological evidence of metastatic lesions on PSMA-PET/CT and/or mpMRI Prostate.
- Number of adverse events reported during and post-administration of radiotracer for PSMA PET/CT.
- Decision curve analysis

ISUP= International Society of urological Pathology; mpMRI= multiparametric magnetic resonance imaging; PSMA=prostate specific membrane antigen; PET/CT=positron emission tomography / computed tomography,

**Sample size and Power Calculation**

The trial will proceed to recruit to an ideally powered sample size of 240 subjects to achieve a power of 0.80. Sample size calculations were based on the primary endpoint of detection of all ISUP grade prostate cancer detection. Area under the receiver operator characteristic (ROC) curve (the AUC), sensitivity and specificity for mpMRI and PSMA-PET/CT are 0.84, 0.603 and 0.89[31], and 0.91, 0.88 and 0.93[32] respectively. The following assumptions were made for sample size calculations: 50% of men who undergo prostate biopsy will be diagnosed with prostate cancer, the proportion of cases (PSMA PET/CT as opposed to mpMRI) is 20% higher, the absolute margin of improvement is 7% (0.35 to 0.42) to declare PSMA-PET/CT is superior, the estimated correlation between the two tests is 80% and a two-sided type I error of 5%. In addition, this sample size makes allowance for a dropout rate of 10%.

*Data management*

Data will be collected onto a password protected files located on the institutional computer, also password protected. Access is given only relevant researchers of this study. The institutional computer is situated in a locked office with only the relevant investigators having access. Data collection is performed by investigators not directly involved in patient care with one investigator collecting data and a second reviewing data independent to ensure completeness. Given the prospective nature of this study, identifiable information is collected for enrolled patients with security measures as detailed above. Range checks will be carried out to promote quality. Data will be audited on a monthly basis to ensure quality. Auditors are investigators independent from sponsors. There is no input from any sponsors to data management. The final trial dataset will be deidentified prior to statistical analysis. The lead investigator as well as those involved in data analysis will have access to the final trial dataset

*Blinding*

Blinding occurs at the level of the clinician reviewing the imaging and biopsy specimens. Separate clinicians review the mpMRI, PSMA-PET/CT and co-registered PMSA-PET/CT and mpMRI images, with each clinician blinded to the results of the other two imaging assessment modalities. The uropathologist will receive tissue samples labelled as a systematic or targeted biopsy and its position, however is blinded to the results of PI-RADS score or PSMA-PET/CT positivity. There is no anticipated need for unblinding of investigator clinicians, as the complete results for each study patient will be viewed by a treating clinicians after all reporting is completed.

*Results and Outcomes*

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Enseignement Supérieur (ABES).

Summary tables will be prepared giving numbers of participants by arm, disease assessment compliance, eligibility infringements and losses to follow-up. Baseline characteristics by treatment arm will be summarized in frequency tables by the use of descriptive statistics for variables. Ninety-five percent confidence intervals (95% CI) for differences between arms of all important endpoints will be calculated, and p-values will be two-sided. Exact tests will be performed with binary outcome data. Data collection forms can be made available upon request.

### *Diagnostic Accuracy*

To determine diagnostic accuracy of PSMA PET/CT compared to mpMRI prostate in the detection of csPCa, findings of imaging will be compared to prostate biopsy histopathology to determine presence or absence of cancer. Clinically significant prostate cancer at prostate biopsy is defined as ISUP Grade Group  $\geq 2$ . For the primary objective, positivity will be defined by histological confirmation of cancer at prostate biopsy.

Accuracy of each diagnostic imaging arm will be assessed by the AUC. mpMRI accuracy will be compared to PSMA PET/CT alone, and in combination with mpMRI. Point estimates of the sensitivity and specificity of each modality alone will be determined, and approximations to their distributions will be estimated using the normal approximation to the binomial distribution. Using independence of the sensitivity and specificity, the AUC will be calculated as the mean of the estimated sensitivity and specificity, and its variance as the sum of the variances of the sensitivity and specificity.

Equivocal lesions will be considered negative for clinical purposes, however these lesions will be targeted during biopsy and a sensitivity analysis will be performed in which lesions rated as equivocal will be considered positive for malignancy. The difference between the AUCs will be used to characterise the true underlying difference between AUC's of the two modalities and to apply a hypothesis test for the existence of a clinically important difference between them (the null hypothesis will be a 7% difference).

Cost evaluations

The potential for cost savings will be evaluated. Considerations included in our analysis are: reductions in prostate biopsy (and efficiencies in consolidation of diagnostic and staging imaging tests) and using software co-registration as an alternative to hybrid PET/MRI machines. Cost evaluations using tools such as a decision curve analysis will be conducted as a secondary outcome. This is preferred as traditional decision-analytical methodologies does not assess clinical consequences and provide results in a continuous form rather than binary[33]. Decision curve analysis will be conducted according to Vickers *et al.*[33] of PSMA PET/CT compared to prostate biopsy results for clinically significant prostate cancer.

Risks of PSMA-PET/CT

Several preclinical and clinical studies have shown the safety of 18F-PSMA. The critical dose-organs are the kidneys (0.0945 mSv/MBq) and urinary bladder (0.085 mSv/MBq) and were calculated from human biodistribution data using OLINDA/EXM (Organ Level Internal Dose Assessment/Exponential Modelling) software. Based on the FDA, a single-organ dose of 0.05 Sv is allowable. This corresponds to an activity of 400 MBq (10.8 mCi) of 18F-PSMA for a 70-100 kg male subject with a prostate cancer, well above the doses used in this study. Accordingly, the effective dose expected to the whole body is 0.0066 Sv, which is below the 0.03 Sv upper limit recommended by the Food and Drug Administration (FDA).

Adverse events and contraindications

No adverse effects due to intravenous administration of 18 F-PSMA for imaging have been reported in the published literature. There are no known contraindications for 18F-PSMA. Overall,18F-PSMA

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Enseignement Supérieur (ABES).

PET scan may be used in clinical research with no risk to subjects with PCa. As such, there is no anticipated additional adverse events from PSMA PET/CT imaging.

Acute adverse events, defined as those experienced by the subject at the time of radiotracer administration and during the two hours following injection will be recorded. Any toxicity will be graded by NCI Common Terminology Criteria for Adverse Events (CTCAE) version 5.0[34].

## Discussion

The drive to accurately detect intraprostatic and extraprostatic disease at the time of prostate cancer diagnosis has led to the intense interest in PSMA-PET/CT as an adjunct to mpMRI prostate. PSMA PET/CT has shown to be highly useful in the setting of high-risk disease and biochemical failure post-radical treatment[35, 36], however its utility as a diagnostic tool for prostate cancer evaluation until recently[22], there has had minimal high-quality prospective data. Our hypothesis is that PSMA-PET/CT will be superior in diagnostic accuracy to mpMRI prostate at identifying cancer within the prostate. As mpMRI prostate is established in its ability to successfully identify prostate cancer, this is a high standard to achieve. Even if PSMA-PET/CT does not supersede mpMRI prostate in diagnostic accuracy, establishing comparable diagnostic accuracy may result in a viable alternative for men who have contraindications to mpMRI.

The use of PSMA intensity as a biomarker shows potential. Roberts *et al.* demonstrated association between 68Ga-PSMA-11 intensity and Gleason score, in addition to upgrading of Gleason score between biopsy and radical prostatectomy results. Specifically, 9 of 14 upgraded patients from biopsy were from Gleason 3+4 to 4+3 on radical prostatectomy histology. This has strong implications for those Gleason 3+4 patients who were initially planned for active surveillance, with the authors suggesting SUVmax of > 8 in Gleason 3+4 malignancy could be a potential prognostic

biological marker of more aggressive disease[21]. While our study utilizes 18F-DCPFyl PSMA, we expect to achieve similar results. Furthermore, several other biomarkers such as the prostate health index have emerged as promising diagnostic implement[3]. The prostate health index showed high accuracy in predicting positive biopsy results[2]. As such, inclusion of biomarkers as part of our study is not ruled out and development of a diagnostic algorithm including biomarkers could improve detection of clinically significant prostate cancer.

The trial may also demonstrate (i) a synergistic effect in cancer diagnosis by the combination of the two imaging techniques, (ii) a benefit for PSMA-PET/CT in men with equivocal mpMRI prostate findings; (iii) benefit for men with concerning clinical features but negative/equivocal mpMRI prostate; and (iv) provide an all-encompassing diagnostic and staging scan for men who have high risk features for metastatic disease at diagnosis. Unlike the PRIMARY trial, our PSMA-PET/CT protocol encompasses chest, abdomen and pelvis, so will be able to add valuable information to this outcome.

Proprietary software from the GE Advantage® Workstation will perform co-registration between mpMRI prostate and PSMA-PET/CT images will be utilised in this trial. Co-registration has potential to improve targeting of prostate biopsy techniques, and help provide an alternative to expensive, difficult to access hybrid PET/MRI machines.

After diagnostic accuracy of PSMA-PET/CT is established, its potential for significant economic impact as a diagnostic test can be thoroughly investigated. Reductions in prostate biopsy, efficiencies in consolidation of diagnostic and staging imaging tests, and using software co-

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Ensignement Supérieur (ABES).

registration as an alternative to hybrid PET/MRI all represent potential economic benefits to our health system.[2, 3]

The PEDAL trial commenced in March 2020, and although recruitment has been delayed due to Covid 19 related adjustments in health care delivery the current aim is to complete recruitment in 36 months. This innovative study will add valuable evidence to demonstrate the diagnostic accuracy of PSMA-PET/CT. It has potential to significantly impact how prostate cancer is diagnosed.

### **Funding statement**

This clinical trial is supported by Cyclotek (Aust) Pty Ltd and their key partners, the Australian Government as part of its CRC Projects Program, General Electrical Healthcare, Macquarie University and the EJ Whitten Prostate Cancer Research Centre at Epworth Healthcare. We are also grateful for philanthropic donations from Reese Limited, the Pitcher and Cicutto families via the St Vincent's Foundation.

Figure 1: PEDAL Trial Schema

## Appendix 1: Multiparametric Magnetic Resonance Imaging Protocol

### IMAGING ACQUISITION:

MRI prostate imaging is acquired as per international guidelines specified by Prostate Imaging-Reporting and Data System, version 2.1 (PIRADS V2.1).

A multi-parametric MRI scan will be performed according to the following technical protocol, consistent with the highest standards of prostate MRI after appropriate bowel preparation (suggest Microlax suppository morning of diagnostic imaging) and buscopan or glucagon injection (where not contraindicated):

- 3-Tesla magnet field strength
- 32-channel cardiac coil, anteriorly and spinal coil posteriorly
- T2 sequences to show pathology, aid localisation of the lesion, and to fuse with ultrasound for those Urologists using co-registration biopsy method.
  - High resolution T2 FSE in 3 planes: axial, coronal and sagittal
  - 3D T2 sequence

Diffusion-Weighted Imaging (DWI) with software derived Apparent Diffusion Co-efficient (ADC) quantitative analysis maps, and multiple b-values (acquired b50, acquired b1400, calculated b2000);

Dynamic Contrast Enhanced imaging (DCE) 3D imaging, with IV gadolinium DTPA bolus determined by body weight, at 2.5ml/second followed by T1 DCE TRICKS (Time-Resolved Imaging of Contrast KineticS).

Analysis of DCEI according to PI-RADS DCEI analytic guidelines using PROCAD software

- No use of Endo-rectal coils or MR Spectroscopy as per current guidelines
- Approximate scan time 30 to 40 minutes

### CONTRAINDICATIONS TO MRI

24 Patient with any contraindication to MRI will not undergo MRI. This includes, but not restricted, to

25 pacemaker or other electronic implants, total hip joint replacement, known metal in the orbit, MR

26 incompatible surgical or cerebral aneurysm clips, shrapnel, non-removable body piercings.

27 **REPORTING OF MPMRI PROSTATE**

28 The mpMRI will be reported by experienced subspecialist Radiologists according to the Prostate

29 Imaging-Reporting and Data System, version 2.1, with each lesion categorised on a scale from 1 to 5.

30 **OPTIMIZATION OF CO-REGISTRATION BETWEEN MPMRI PROSTATE AND PSMA-PET/CT**

31 To enable better co-registration of mpMRI to PSMA-PET/CT:

- 32 • option to use of suppositories to help eliminate gas/faeces from rectum
- 33 • ensure flat pelvis
- 34 • Use of structured knee bolster and strapping of feet to aid pelvic alignment

**Appendix 3: 18F-DCFPyL PSMA administration and PET/CT Imaging Protocol**

**RADIOPHARMACEUTICAL**

18F DCFPyL will be produced at Cyclotek (Aust) Pty Ltd under GMP Licence Number MI-12092005-LI-000904-2 and (parametric) release after certain quality control tests are performed and transported to the imaging site under regulatory criteria for dangerous goods. Cyclotek will provide the imaging site with a Quality Control Release notification form. Patients will complete the radiopharmaceutical consent form at their local site prior to injection.

**18F-DCFPYL PSMA INJECTION DOSING AND ADMINISTRATION**

Patients will be administered a single, intravenous 250MBq bolus dose of 18F-DCFPyL PSMA (acceptable: 200-300MBq depending on patient weight and activity provided on day of scan). The administered activity of 18F-DCFPyL PSMA is approximately 3MBq per kilogram body weight up to 350 maximum dose.

**18F-PSR PET/CT imaging protocol for initial diagnosis/staging of Prostate Ca Imaging Protocol**

**Patient Preparation:**

- No fasting required. (\*Must be well hydrated, approximately 1-2 litres of plain water in the 2 hours before appointment.)
- The activity is administered intravenously through a cannula either utilising the automatic injector and a 100ml Saline bag or via hand injection through the cannula utilising the 5ml syringe shield and 2x10mls saline flushes.
- The dose pre and post syringe activities and times must be recorded to work out the exact administered activity for the injection time.
- Uptake Time: 120 minutes post 18F-DCFPyL injection. The patient is free to leave the department if they wish during this waiting time.

- Patient to void before the scan

## SCANNER

Patients will be imaged on a GE Discovery 690 or 710 PET/CT (General Electric Medical Systems, Milwaukee, WI) combining a 64 slice multidetector CT scanner with a dedicated, full ring PET scanner with lutetium-based crystals.

## Scan:

*Scan range:* Mid/Upper thighs to Lung Apices. Patient position supine, arms up and feet first to ensure bladder is in its emptiest state. CT scan acquired using a low-dose protocol (120/140 kVp and automatic exposure control ('Smart mA', max 200mA). Low-dose attenuation correction CT images were acquired and reconstructed to a 3.75mm slice thickness with an increment of 3.27mm using iterative reconstruction (50% ASiR). PET images were acquired at 3.5min/bed through the pelvis and 3.0min/bed to the lung apices. PET images were reconstructed from time of flight emission data using VUE Point FX and Q-Clear™ iterative technique with  $\beta$  value of 400. Q-Clear™ is a fully convergent reconstruction method which incorporates point spread function corrections, scatter correction and ULD-CT attenuation corrections. Sharp IR function was applied with no Z-axis filter. PET images were reconstructed on a 256 matrix.

PET/CT 18F-PSR <90kg 120min post injection

SPIRIT 2013 Checklist: Recommended items to address in a clinical trial protocol and related documents\*

Section/item	Item No	Description	Addressed on page number
<b>Administrative information</b>			
Title	1	Descriptive title identifying the study design, population, interventions, and, if applicable, trial acronym	<u>1</u>
Trial registration	2a	Trial identifier and registry name. If not yet registered, name of intended registry	<u>143-145</u>
	2b	All items from the World Health Organization Trial Registration Data Set	<u>145</u>
Protocol version	3	Date and version identifier	<u>145</u>
Funding	4	Sources and types of financial, material, and other support	<u>192-198, 419-424</u>
Roles and responsibilities	5a	Names, affiliations, and roles of protocol contributors	<u>5-24, 437-460</u>
	5b	Name and contact information for the trial sponsor	<u>420-425</u>
	5c	Role of study sponsor and funders, if any, in study design; collection, management, analysis, and interpretation of data; writing of the report; and the decision to submit the report for publication, including whether they will have ultimate authority over any of these activities	<u>151-153</u>
	5d	Composition, roles, and responsibilities of the coordinating centre, steering committee, endpoint adjudication committee, data management team, and other individuals or groups overseeing the trial, if applicable (see Item 21a for data monitoring committee)	<u>Not applicable</u>

<b>Introduction</b>			
Background and rationale	6a	Description of research question and justification for undertaking the trial, including summary of relevant studies (published and unpublished) examining benefits and harms for each intervention	<u>129-139</u>
	6b	Explanation for choice of comparators	<u>165-171</u>
Objectives	7	Specific objectives or hypotheses	<u>269-275</u>
Trial design	8	Description of trial design including type of trial (eg, parallel group, crossover, factorial, or single group), allocation ratio, and framework (eg, superiority, equivalence, noninferiority, exploratory)	<u>165-172</u>
<b>Methods: Participants, interventions, and outcomes</b>			
Study setting	9	Description of study settings (eg, community clinic, academic hospital) and list of countries where data will be collected. Reference to where list of study sites can be obtained	<u>427-433</u>
Eligibility criteria	10	Inclusion and exclusion criteria for participants. If applicable, eligibility criteria for study centres and individuals who will perform the interventions (eg, surgeons, psychotherapists)	<u>183</u>
Interventions	11a	Interventions for each group with sufficient detail to allow replication, including how and when they will be administered	<u>165-172</u>
	11b	Criteria for discontinuing or modifying allocated interventions for a given trial participant (eg, drug dose change in response to harms, participant request, or improving/worsening disease)	<u>Not applicable</u>
	11c	Strategies to improve adherence to intervention protocols, and any procedures for monitoring adherence (eg, drug tablet return, laboratory tests)	<u>Not applicable</u>
	11d	Relevant concomitant care and interventions that are permitted or prohibited during the trial	<u>179-181</u>
Outcomes	12	Primary, secondary, and other outcomes, including the specific measurement variable (eg, systolic blood pressure), analysis metric (eg, change from baseline, final value, time to event), method of aggregation (eg, median, proportion), and time point for each outcome. Explanation of the clinical relevance of chosen efficacy and harm outcomes is strongly recommended	<u>277</u>
Participant timeline	13	Time schedule of enrolment, interventions (including any run-ins and washouts), assessments, and visits for participants. A schematic diagram is highly recommended (see Figure)	<u>154</u>

Sample size	14	Estimated number of participants needed to achieve study objectives and how it was determined, including clinical and statistical assumptions supporting any sample size calculations	<u>280-290</u>
Recruitment	15	Strategies for achieving adequate participant enrolment to reach target sample size	<u>289-290</u>
<b>Methods: Assignment of interventions (for controlled trials)</b>			
Allocation:			
Sequence generation	16a	Method of generating the allocation sequence (eg, computer-generated random numbers), and list of any factors for stratification. To reduce predictability of a random sequence, details of any planned restriction (eg, blocking) should be provided in a separate document that is unavailable to those who enrol participants or assign interventions	<u>Not applicable</u>
Allocation concealment mechanism	16b	Mechanism of implementing the allocation sequence (eg, central telephone; sequentially numbered, opaque, sealed envelopes), describing any steps to conceal the sequence until interventions are assigned	<u>Not applicable</u>
Implementation	16c	Who will generate the allocation sequence, who will enrol participants, and who will assign participants to interventions	<u>Not applicable</u>
Blinding (masking)	17a	Who will be blinded after assignment to interventions (eg, trial participants, care providers, outcome assessors, data analysts), and how	<u>305-312</u>
	17b	If blinded, circumstances under which unblinding is permissible, and procedure for revealing a participant's allocated intervention during the trial	<u>310-312</u>
<b>Methods: Data collection, management, and analysis</b>			
Data collection methods	18a	Plans for assessment and collection of outcome, baseline, and other trial data, including any related processes to promote data quality (eg, duplicate measurements, training of assessors) and a description of study instruments (eg, questionnaires, laboratory tests) along with their reliability and validity, if known. Reference to where data collection forms can be found, if not in the protocol	<u>292-303</u>
	18b	Plans to promote participant retention and complete follow-up, including list of any outcome data to be collected for participants who discontinue or deviate from intervention protocols	<u>189-190</u>

1	Data management	19	Plans for data entry, coding, security, and storage, including any related processes to promote data quality (eg, double data entry; range checks for data values). Reference to where details of data management procedures can be found, if not in the protocol	<u>287-291</u>
2				
3				
4				
5	Statistical methods	20a	Statistical methods for analysing primary and secondary outcomes. Reference to where other details of the statistical analysis plan can be found, if not in the protocol	<u>314-320</u>
6				
7				
8		20b	Methods for any additional analyses (eg, subgroup and adjusted analyses)	<u>314-320</u>
9				
10		20c	Definition of analysis population relating to protocol non-adherence (eg, as randomised analysis), and any statistical methods to handle missing data (eg, multiple imputation)	<u>289-290</u>
11				
12				
13				
14	<b>Methods: Monitoring</b>			
15				
16	Data monitoring	21a	Composition of data monitoring committee (DMC); summary of its role and reporting structure; statement of whether it is independent from the sponsor and competing interests; and reference to where further details about its charter can be found, if not in the protocol. Alternatively, an explanation why a DMC is not needed	<u>291</u>
17				
18				
19				
20				
21				
22		21b	Description of any interim analyses and stopping guidelines, including who will have access to these interim results and make the final decision to terminate the trial	<u>Not applicable</u>
23				
24				
25	Harms	22	Plans for collecting, assessing, reporting, and managing solicited and spontaneously reported adverse events and other unintended effects of trial interventions or trial conduct	<u>362-369</u>
26				
27				
28	Auditing	23	Frequency and procedures for auditing trial conduct, if any, and whether the process will be independent from investigators and the sponsor	<u>300-301</u>
29				
30				
31				
32	<b>Ethics and dissemination</b>			
33				
34	Research ethics approval	24	Plans for seeking research ethics committee/institutional review board (REC/IRB) approval	<u>144-146</u>
35				
36				
37	Protocol amendments	25	Plans for communicating important protocol modifications (eg, changes to eligibility criteria, outcomes, analyses) to relevant parties (eg, investigators, REC/IRBs, trial participants, trial registries, journals, regulators)	<u>171-172</u>
38				
39				
40				
41				
42				
43				
44				
45				
46				

Consent or assent	26a	Who will obtain informed consent or assent from potential trial participants or authorised surrogates, and how (see Item 32)	<u>175-177</u>
	26b	Additional consent provisions for collection and use of participant data and biological specimens in ancillary studies, if applicable	<u>175-177</u>
Confidentiality	27	How personal information about potential and enrolled participants will be collected, shared, and maintained in order to protect confidentiality before, during, and after the trial	<u>292-303</u>
Declaration of interests	28	Financial and other competing interests for principal investigators for the overall trial and each study site	<u>434-436</u>
Access to data	29	Statement of who will have access to the final trial dataset, and disclosure of contractual agreements that limit such access for investigators	<u>301-303</u>
Ancillary and post-trial care	30	Provisions, if any, for ancillary and post-trial care, and for compensation to those who may suffer harm from trial participation	<u>362-366</u>
Dissemination policy	31a	Plans for investigators and sponsor to communicate trial results to participants, healthcare professionals, the public, and other relevant groups (eg, via publication, reporting in results databases, or other data sharing arrangements), including any publication restrictions	<u>64-68</u>
	31b	Authorship eligibility guidelines and any intended use of professional writers	<u>67-68</u>
	31c	Plans, if any, for granting public access to the full protocol, participant-level dataset, and statistical code	Protocol submitted for publication
<b>Appendices</b>			
Informed consent materials	32	Model consent form and other related documentation given to participants and authorised surrogates	<u>See attached</u>
Biological specimens	33	Plans for collection, laboratory evaluation, and storage of biological specimens for genetic or molecular analysis in the current trial and for future use in ancillary studies, if applicable	<u>Not applicable</u>

\*It is strongly recommended that this checklist be read in conjunction with the SPIRIT 2013 Explanation & Elaboration for important clarification on the items. Amendments to the protocol should be tracked and dated. The SPIRIT checklist is copyrighted by the SPIRIT Group under the Creative Commons “Attribution-NonCommercial-NoDerivs 3.0 Unported” license.
