

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email info.bmjopen@bmj.com

ABSTRACT

Introduction Micronutrient deficiencies are common in developing countries and are usually related to inadequate food intake, poor diet quality, and low bioavailability. Copper, selenium and zinc are essential minerals in several enzymatic reactions and their deficiencies are associated with worse prognosis in pregnancy, compromising maternal health as well as her offspring.

Methods and analysis The search will be performed by independent reviewers. The bases used will be PubMed/MEDLINE, Science direct, Lilacs, Adolec, Scopus, EMBASE, CINAHL, Web of Science, CENTRAL, IMSEAR, PAHOS, WPRIM, IMEMR, AIM for grey literature OpenGrey and OVID. National data will be searched in BDTD. Risk of bias assessment will be performed using the Joanna Briggs group prevalence study checklist. The Newcastle-Ottawa scale will be used to evaluate the methodological quality. Combinable studies will be performed meta-analysis. Heterogeneity will be tested using Cochran's Q test and quantified by the inconsistency test (I²). In the presence of high heterogeneity, meta-analysis will be performed using the random effects model with Stata metaprop. Summary prevalence will be generated for each outcome, presented in Forest plot figures.

Ethics and dissemination This systematic review will be solely based on published and retrievable literature, no ethics approval will be obtained. Our dissemination strategy will involve the presentation in scientific meetings, as well as the publication of article(s), posters and presentations in congresses.

PROSPERO Registration number CRD42020165352.

Keywords: Women, Fertility, Copper, Selenium, Zinc, systematic review, meta-analysis

Strengths and limitations of this study:

Micronutrient deficiency in women of childbearing age generates negative maternal health outcomes for their offspring. Considering that this is the first systematic review that will evaluate the prevalence of copper, selenium and zinc deficiencies in women of childbearing age worldwide, this is the main strength of the study. Also, this systematic review and meta-analysis has been carried out under rigorous methodology and following the recommendations of PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses)¹ and Cochrane Collaboration²

Considering the limitations, obtaining some articles in their entirety has been a challenge, as they are very old since we did not limit date for the publications. However, the authors have been contacted and some of them have sent the full articles.

For peer review only

BACKGROUND:

Micronutrient deficiencies are common in many developing countries and are usually related to inadequate food intake, poor diet quality, low bioavailability (due to the presence of inhibitors, preparation mode and interactions) and/or the presence of infections, and are of growing public health concern³. Although the focus of discussions on micronutrient deficiency is around three main problems-vitamin A deficiency (VAD), iodine deficiency disorders (IDD), and iron deficiency anemia (IDA)-with higher prevalences in low-income settings, zinc, selenium, and copper deficiencies have stood out as a cause for concern worldwide, regardless of socioeconomic status⁴. Copper, selenium and zinc are essential minerals in several enzymatic reactions and their deficiencies are associated with worse prognosis in pregnancy, compromising maternal health as well as her offspring⁵⁻⁷.

Considering women of childbearing age, the consequences of deficiencies of these micronutrients affect not only these individuals, but also their offspring. These women are susceptible to maternal and fetal deficiencies, affecting future generations⁸. The developmental period in utero is critical for the health of the child, both at birth and long after. Micronutrient deficiencies in women of childbearing age can be exacerbated during pregnancy, increasing the risk of maternal and child complications. Maternal exposure to environmental hazards during pregnancy can therefore have a major impact on child health⁹.

Thus, knowing the global, regional, and national prevalence of these nutritional deficiencies and their social determinants is of fundamental importance for planning policies and programs aimed at women's health in order to reduce the incidence of diseases associated with micronutrient deficiencies, as well as possible negative outcomes in pregnant women and infants.

METHODS AND ANALYSIS

Search strategy

This is the protocol of a systematic review with meta-analysis to identify the global, regional and national prevalence of zinc, selenium and copper deficiencies in women of childbearing age. The study will be developed based on the recommendations of PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocol)¹ and the protocol has been registered in the International Prospective Register of Systematic Reviews (PROSPERO)¹⁰.

The search will be performed by two independent reviewers (T.C.C and J.C.D.P). The controlled terms will be searched on the MeSH, Decs and ENTREE platforms. The search will be done in PubMed/MEDLINE, Science direct, LILACS, ADOLEC, Scopus, EMBASE, CINAHL, Web of Science, Cochrane Central Register of Controlled Trials (CENTRAL), Index Medicus for the South-East Asia Region (IMSEAR), Pan American Health Organization (PAHOS), Index Medicus for the Western Pacific (WPRIM), Index Medicus of the Eastern Mediterranean (IMEMR) and African Index Medicus (AIM). In order to saturate the searches, manual searches will be conducted with analysis of reference lists of included articles and relevant reviews, contact with authors of included studies, study registries and grey literature in OpenGrey and OVID platforms. For national data approach, results of CAPES theses and dissertations and the Digital Library of Theses and Dissertations (BDTD) will be searched.

Inclusion criteria for study designs

Observational cohort or cross-sectional studies and intervention studies with data on micronutrient deficiency before the intervention and with women of childbearing age as the population group will be included.

Studies in which participants were supplemented with micronutrients (copper, selenium, and zinc) or studies in which participants were selected because they belonged to a group with chronic or high-risk diseases will be excluded. Due to inability to calculate prevalence, case-control articles will also be excluded. Review studies and case reports, in vitro and in vivo studies, book chapters, and any other studies that did not assess prevalence or provide data for possible calculations will also be excluded. There will be no limitations related to language or year of publication, and no search filters will be used.

Qualitative and quantitative studies will be searched, with no date limits, language of publication, or search filter. Search strategies will be developed by a Health Sciences Librarian with experience in systematic reviews. Every strategy will be developed with input from the project. An outline of the search strategy for the PUBMED platform is provided in Appendix 1.

Study selection

The entire search process will be exported to the Rayyan software (Rayyan QCRI/ web app), initiating the screening stage. Duplicate publications will be excluded to reduce the risk of bias. After this step, we will start reading the title and abstract to select the eligible publications

(step I). Studies meeting the criteria will be directed to full-text reading (step II); if necessary, reviewers will contact study authors to obtain additional information to help make the decision about study inclusion in the review. After reading the full text, only studies that meet the pre-established eligibility criteria will be selected. All these steps will be performed by two independent reviewers (T.C.C. and J.C.D.P.) and a third reviewer (P.R.F.C.) will be consulted in case of disagreement.

A flowchart will be prepared accounting for the total number of articles found in the search, selected for screening, eligible for reading in full, included and excluded from the review. After reading in full, all articles that do not meet the eligibility criteria will be excluded and the reasons for this decision will be reported in a spreadsheet to compose the flowchart of study selection. In the manual search, the reference lists of the included articles will be examined, as well as the reviews on the topic, and the team will decide together which studies will be selected for synthesis and data extraction.

Data extraction and data items

After reading and selecting the included articles, data synthesis and extraction will begin. The entire process will be documented in Microsoft Excel software. The information collected will be study identification, study characteristics, participant characteristics, diagnosis and classification of the condition, prevalence, incidence and factors associated with the condition, as presented in table 1.

Table 1 - Information collection

Identification of the study	Title, first author's last name, year of publication, journal, volume, number and pages.
Study characteristics	Participant recruitment period, country, region, study design, study site, study setting, sampling process, data collection time, sample size.
Participant Characteristics	Information on study inclusion and exclusion criteria, mean/median age,

	ethnicity, proportion of participants with any therapy.
Diagnosis and classification of the condition	Measurement or diagnostic criteria used to define the condition (micronutrient deficiency), micronutrient evaluated, unit of measurement, cut-off point adopted.
Prevalence and incidence	Number of participants, total person follow-up time, number of cases of the condition, reported etiologies, prevalence, incidence rate, and their respective confidence intervals and/or p-value.

In the absence of necessary information, the team will contact the authors of the study (maximum of three attempts by e-mail), and the entire process will be documented and logged. The identification of duplicate, overlapping, or complementary articles (multiple articles from the same study) will be performed by identifying the registration numbers of the clinical trials, the authors' names, the city and location of the study (institutions, schools, hospitals, etc.), specific details of the study methodology, date and duration of the study (when applicable). If questions remain, the authors of the articles will be contacted.

Every extraction step will be performed by two previously trained reviewers. Legends will be elaborated with the objective of simplifying the data extraction spreadsheet.

Outcome assessment

The main outcome of this review is the identification of the global, regional (by continent) and national prevalence of zinc, selenium and copper deficiencies in women of childbearing age. These results can serve as a reference for the production of other works in the area, besides making public relevant data on women's health worldwide, supporting citations of this content by other authors, thus increasing the visibility of scientific production and contributing to the knowledge about the deficiency of these micronutrients in the target audience.

Risk of bias assessment strategy

allows you to model intra-study variability using the binomial distribution. That is, it makes the data distribution normal and stabilizes variances¹². The inverse function of the double sine-arc transformation has also been derived in the literature to recover the original proportion scale after data aggregation¹² while maintaining the interpretability of the final result. Thus, we will generate the summary prevalence for each outcome, as well as its respective 95% confidence interval, presented in Forest plot figures.

Potential variables that may influence the high heterogeneity among studies will be investigated by means of subgroup analysis (for dichotomous variables: age group, ethnicity, socioeconomic status, dosage form [blood or serum], cutoff point adopted, and anthropometric status) and meta-regression (for continuous variables: mean age, sample size, and mean BMI).

If ten or more studies are included in the meta-analysis, Egger's test and the funnel plot will be adopted to assess publication bias. In the funnel plot, the graphic funnel shape makes a qualitative assessment of the possibility of bias, in which asymmetries indicate the presence of publication bias. Egger's test will be applied when the variables are dichotomous or when the distribution of effects is normal (continuous variables); otherwise (asymmetric distribution), Begg's test will be applied. A strong probability that the distribution is not by chance, i.e., presence of publication bias, is suggested when p value <0.05².

Ethics, dissemination data protection

Ethical approval was not obtained since the data to be collected and analyzed cannot be linked to specific individuals.

Patient and public involvement

Since this will be a systematic review, there will be no direct patient or public involvement.

Ethics and dissemination

This systematic review will allow the identification of the prevalence of copper, selenium and zinc deficiencies in women of childbearing age at the global, regional and national (Brazil) levels and will serve as a reference for the production of other works in the area, besides making public relevant data on women's health in Brazil and in the world, supporting citations of this content by other authors, thus increasing the visibility of the national scientific production and the Brazilian contribution to the world scientific knowledge.

Our dissemination strategy will involve the presentation in scientific meetings, as well as the publication of article(s) in international journals, peer-reviewed and open access, preparation of posters and oral presentations in Congresses and scientific events at national and international level, in the areas of nutrition and public health.

Acknowledgements

We would like to thank the whole NUBASE team for all the support in the elaboration of this project.

Contributions: P.R.C.F. supervised the study and contributed to study conception, design, and manuscript drafting. T.C.C contributed to study conception, design, and manuscript drafting. J.C.D.P. contributed to study conception, design, and manuscript drafting. M.L.P.S contributed to study conception, design, and manuscript drafting. S.K. contributed to study conception, design, and manuscript drafting. L.P contributed to study conception, design, and manuscript drafting. All authors critically reviewed and approved the final manuscript for submission.

Funding: This work was supported by the research promotion foundation CNPq, Call MS-SCTIE-Decit/CNPq N° 26/2019 - Research in Food and Nutrition. Funders are not directly involved in project.

Competing interests: This research has no conflict of interest.

Patient consent for publication: Not required.

Reporting checklist for protocol of a systematic review and meta analysis.

Based on the PRISMA-P guidelines.

Instructions to authors

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the PRISMA-Reporting guidelines, and cite them as:

ABSTRACT

Introduction Micronutrient deficiencies are common in developing countries and are usually related to inadequate food intake, poor diet quality, and low bioavailability. Copper, selenium and zinc are essential minerals in several enzymatic reactions and their deficiencies are associated with worse prognosis in pregnancy, compromising maternal health as well as her offspring.

Methods and analysis The search will be performed by independent reviewers. The bases used will be PubMed/MEDLINE, Science direct, Lilacs, Adolec, Scopus, EMBASE, CINAHL, Web of Science, CENTRAL, IMSEAR, PAHOS, WPRIM, IMEMR, AIM for grey literature OpenGrey and OVID. National data will be searched in BDTD. All search was performed on 10/2021 and updated on 10/2022. Risk of bias assessment will be performed using the Joanna Briggs group prevalence study checklist. Combinable studies will be performed meta-analysis. Heterogeneity will be tested using Cochran's Q test and quantified by the inconsistency test (I^2). In the presence of high heterogeneity, meta-analysis will be performed using the random effects model with Stata metaprop. Summary prevalence will be generated for each outcome, presented in Forest plot figures.

Ethics and dissemination This systematic review will be solely based on published and retrievable literature, no ethics approval will be obtained. Our dissemination strategy will involve the presentation in scientific meetings, as well as the publication of article(s), posters and presentations in congresses.

PROSPERO Registration number CRD42020165352.

Keywords: Women, Fertility, Copper, Selenium, Zinc, systematic review, meta-analysis

Strengths and limitations of this study:

- First systematic review that will assess the prevalence of copper, selenium and zinc deficiencies in women of childbearing age worldwide.
- A thorough and highly sensitive search strategy in leading databases, with no geographic or language restrictions, will be conducted by a multidisciplinary team with experience in systematic review.
- Different cut-off points.
- Heterogeneity among studies.

1

2

3

4 **BACKGROUND:**

5

6 Micronutrient deficiencies are common in many developing countries and are usually

7 related to inadequate food intake, poor diet quality, low bioavailability (due to the presence of

8 inhibitors, preparation mode and interactions) and/or the presence of infections, and are of growing

9 public health concern^{1,2}. Although the focus of discussions on micronutrient deficiency is around

10 three main problems-vitamin A deficiency (VAD), iodine deficiency disorders (IDD), and iron

11 deficiency anemia (IDA)-with higher prevalences in low-income settings, zinc, selenium, and

12 copper deficiencies have stood out as a cause for concern worldwide, regardless of socioeconomic

13 status^{2,3}. Copper, selenium and zinc are essential minerals in several enzymatic reactions and their

14 deficiencies may be associated with worse prognosis in pregnancy. Deficiencies may increase the

15 risk of premature labor. But there are still contradictions⁴⁻⁶.

16

17 Considering women of childbearing age, the consequences of deficiencies of these

18 micronutrients can affect not only these individuals, but also their offspring. These women are

19 susceptible to maternal and fetal deficiencies, affecting future generations⁷. The developmental

20 period in utero is critical for the health of the child, both at birth and long after. Micronutrient

21 deficiencies in women of childbearing age can be exacerbated during pregnancy, increasing the

22 risk of maternal and child complications². Maternal exposure to environmental hazards during

23 pregnancy can therefore have a major impact on child health⁸.

24

25 Thus, knowing the global, regional, and national prevalence of these nutritional deficiencies

26 and their social determinants is of fundamental importance for planning policies and programs

27 aimed at women's health in order to reduce the incidence of diseases associated with micronutrient

28 deficiencies, as well as possible negative outcomes in pregnant women and infants.

29

30 Question formulation: What is the prevalence of copper, selenium and zinc deficiencies in

31 women of childbearing age?

32

33

34

35 **METHODS AND ANALYSIS**

36

37

38

39 **Search strategy**

40

41 This is the protocol of a systematic review with meta-analysis to identify the global,

42 regional and national prevalence of zinc, selenium and copper deficiencies in women of

43 childbearing age. The study will be developed based on the recommendations of PRISMA-P

44 (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocol)⁹ and the protocol

has been registered in the International Prospective Register of Systematic Reviews (PROSPERO)¹⁰.

The search will be performed by two independent reviewers (T.C.C and J.C.D.P) and a third reviewer (P.R.F.C.) will be consulted in case of disagreement. The controlled terms will be searched on the MeSH, Decs and ENTREE platforms. The search will be done in PubMed/MEDLINE, Science direct, LILACS, ADOLEC, Scopus, EMBASE, CINAHL, Web of Science, Cochrane Central Register of Controlled Trials (CENTRAL), Index Medicus for the South-East Asia Region (IMSEAR), Pan American Health Organization (PAHOS), Index Medicus for the Western Pacific (WPRIM), Index Medicus of the Eastern Mediterranean (IMEMR) and African Index Medicus (AIM). In order to saturate the searches, manual searches will be conducted with analysis of reference lists of included articles and relevant reviews, contact with authors of included studies, study registries and grey literature in OpenGrey and OVID platforms. For national data approach, results of CAPES theses and dissertations and the Digital Library of Theses and Dissertations (BDTD) will be searched. All search was performed on 10/2021 and updated on 10/2022.

Inclusion criteria for study designs

Observational cohort or cross-sectional studies and intervention studies with data on micronutrient deficiency before the intervention and with women of childbearing age as the population group will be included. Although most studies consider fertile age 15 to 49 years^{11–13}. In this study, this group will be 10 and 49 years old, by request of the Brazilian Ministry of Health.

Studies in which participants were supplemented with micronutrients (copper, selenium, and zinc) or studies in which participants were selected because they belonged to a group with chronic or high-risk diseases will be excluded. Due to inability to calculate prevalence, case-control articles will also be excluded. Review studies and case reports, in vitro and in vivo studies, book chapters, and any other studies that did not assess prevalence or provide data for possible calculations will also be excluded. There will be no limitations related to language or year of publication, and no search filters will be used.

Qualitative and quantitative studies will be searched, with no date limits, language of publication, or search filter. Search strategies will be developed by a Health Sciences Librarian with experience in systematic reviews. Every strategy will be developed with input from the project. An outline of the search strategy for the PUBMED platform is provided in Appendix 1.

Study selection

The entire search process will be exported to the Rayyan software (Rayyan QCRI/ web app), initiating the screening stage. Duplicate publications will be excluded to reduce the risk of bias. After this step, we will start reading the title and abstract to select the eligible publications (step I). Studies meeting the criteria will be directed to full-text reading (step II); if necessary, reviewers will contact study authors to obtain additional information to help make the decision about study inclusion in the review. After reading the full text, only studies that meet the pre-established eligibility criteria will be selected. All these steps will be performed by two independent reviewers (T.C.C. and J.C.D.P.) and a third reviewer (P.R.F.C.) will be consulted in case of disagreement.

A flowchart will be prepared accounting for the total number of articles found in the search, selected for screening, eligible for reading in full, included and excluded from the review. After reading in full, all articles that do not meet the eligibility criteria will be excluded and the reasons for this decision will be reported in a spreadsheet to compose the flowchart of study selection. In the manual search, the reference lists of the included articles will be examined, as well as the reviews on the topic, and the team will decide together which studies will be selected for synthesis and data extraction.

Data extraction and data items

After reading and selecting the included articles, data synthesis and extraction will begin. The entire process will be documented in Microsoft Excel software. The information collected will be study identification, study characteristics, participant characteristics, diagnosis and classification of the condition, prevalence, incidence and factors associated with the condition, as presented in table 1.

Table 1 - Information collection

Identification of the study	Title, first author's last name, year of publication, journal, volume, number and pages.
Study characteristics	Participant recruitment period, country, region, study design, study site, study

	setting, sampling process, data collection time, sample size.
Participant Characteristics	Information on study inclusion and exclusion criteria, mean/median age, ethnicity, proportion of participants with any therapy.
Diagnosis and classification of the condition	Measurement or diagnostic criteria used to define the condition (micronutrient deficiency), micronutrient evaluated, unit of measurement, cut-off point adopted.
Prevalence and incidence	Number of participants, total person follow-up time, number of cases of the condition, reported etiologies, prevalence, incidence rate, and their respective confidence intervals and/or p-value.

In the absence of necessary information, the team will contact the authors of the study (maximum of three attempts by e-mail), and the entire process will be documented and logged. The identification of duplicate, overlapping, or complementary articles (multiple articles from the same study) will be performed by identifying the registration numbers of the clinical trials, the authors' names, the city and location of the study (institutions, schools, hospitals, etc.), specific details of the study methodology, date and duration of the study (when applicable). If questions remain, the authors of the articles will be contacted.

Every extraction step will be performed by two previously trained reviewers. Legends will be elaborated with the objective of simplifying the data extraction spreadsheet.

Outcome assessment

The main outcome of this review is the identification of the global, regional (by continent) and national prevalence of zinc, selenium and copper deficiencies in women of childbearing age. These results can serve as a reference for the production of other works in the area, besides making public relevant data on women's health worldwide, supporting citations of this content by other

1
2
3
4 authors, thus increasing the visibility of scientific production and contributing to the knowledge
5 about the deficiency of these micronutrients in the target audience.
6
7

8
9 **Risk of bias assessment strategy**

10
11 The evaluation of the risk of bias will be performed using the critical appraisal checklist for
12 prevalence studies¹⁴. This checklist contains 9 items of questions regarding the sample, data
13 collection, and statistical procedures used in the study. The response options are "yes", "no",
14 "unclear" or "not applicable". The Newcastle-Ottawa scale will be used to evaluate the
15 methodological quality¹⁵.
16
17

18
19 All studies, regardless of their quality score, will be included in this review and the
20 sensitivity analysis will assess the relevance of methodological quality in the final result. Both steps
21 will be performed independently by two experienced and trained reviewers, and in case of
22 disagreement a third reviewer will break the tie.
23
24
25

26
27 **Analysis, data synthesis, publication bias and reporting**

28
29 From these extracted data, a qualitative synthesis will be carried out structured around the
30 prevalence of the deficiencies/inabilities identified in the studies, measurement units and cutoff
31 points adopted, evaluating these results by country and socioeconomic situation (low, lower-
32 middle, upper-middle, and high income countries).
33
34

35
36 For combinatorial studies¹⁶, quantitative synthesis of data will be performed using meta-
37 analysis. The extent of heterogeneity of the meta-analysis will be tested using Cochran's Q test and
38 quantified by the inconsistency test (I^2 statistic). This statistic determines the magnitude of
39 heterogeneity by the proportion of the total variation between studies due to heterogeneity¹⁶. A p-
40 value is often cited as an indication of the extent of variability between studies. Therefore, the chi-
41 square test will be employed to assess the significance of heterogeneity. A significance level of p-
42 value <0.10 will be used to detect true heterogeneity among study results¹⁶.
43
44
45
46

47
48 The magnitude of heterogeneity will be identified by calculating I^2 , which ranges from 0 to
49 100%. Thus, I^2 close to zero suggests that all the dispersion can be attributed to the random error
50 of the study, i.e., there is no heterogeneity. If an I^2 value close to 25% is calculated, it indicates low
51 heterogeneity among studies; higher than 50% indicates moderate heterogeneity; and, above 75%,
52 high heterogeneity¹⁶.
53
54
55
56

In the presence of high heterogeneity, meta-analysis will be performed using the random effects model conducted with Stata's metaprop command. It allows the computation of 95% confidence intervals using the score statistic and the exact binomial method, as well as incorporating FreemanTukey's double-sine-arc transformation of proportions. This method also allows you to model intra-study variability using the binomial distribution. That is, it makes the data distribution normal and stabilizes variances¹⁷. The inverse function of the double sine-arc transformation has also been derived in the literature to recover the original proportion scale after data aggregation¹⁷ while maintaining the interpretability of the final result. Thus, we will generate the summary prevalence for each outcome, as well as its respective 95% confidence interval, presented in Forest plot figures.

Potential variables that may influence the high heterogeneity among studies will be investigated by means of subgroup analysis (for dichotomous variables: age group, ethnicity, socioeconomic status, dosage form [blood or serum], cutoff point adopted, and anthropometric status) and meta-regression (for continuous variables: mean age, sample size, and mean BMI).

If ten or more studies are included in the meta-analysis, Egger's test and the funnel plot will be adopted to assess publication bias. In the funnel plot, the graphic funnel shape makes a qualitative assessment of the possibility of bias, in which asymmetries indicate the presence of publication bias. Egger's test will be applied when the variables are dichotomous or when the distribution of effects is normal (continuous variables); otherwise (asymmetric distribution), Begg's test will be applied. A strong probability that the distribution is not by chance, i.e., presence of publication bias, is suggested when p value <0.05¹⁶.

Ethics, dissemination data protection

Ethical approval was not obtained since the data to be collected and analyzed cannot be linked to specific individuals.

Patient and public involvement

Since this will be a systematic review, there will be no direct patient or public involvement.

Ethics and dissemination

This systematic review will allow the identification of the prevalence of copper, selenium and zinc deficiencies in women of childbearing age at the global, regional and national (Brazil)

1
2
3
4 levels and will serve as a reference for the production of other works in the area, besides making
5 public relevant data on women's health in Brazil and in the world, supporting citations of this
6 content by other authors, thus increasing the visibility of the national scientific production and the
7 Brazilian contribution to the world scientific knowledge.
8
9

10
11 Our dissemination strategy will involve the presentation in scientific meetings, as well as
12 the publication of article(s) in international journals, peer-reviewed and open access, preparation
13 of posters and oral presentations in Congresses and scientific events at national and international
14 level, in the areas of nutrition and public health.

Reporting checklist for protocol of a systematic review and meta analysis.

Based on the PRISMA-P guidelines.

Instructions to authors

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the PRISMA-Reporting guidelines, and cite them as:

Moher D, Shamseer L, Clarke M, Gherzi D, Liberati A, Petticrew M, Shekelle P, Stewart LA. Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols (PRISMA-P) 2015 statement. Syst Rev. 2015;4(1):1.

ABSTRACT

Introduction Micronutrient deficiencies are common in developing countries and are usually related to inadequate food intake, poor diet quality, and low bioavailability. Copper, selenium and zinc are essential minerals in several enzymatic reactions and their deficiencies are associated with worse prognosis in pregnancy, compromising maternal health as well as her offspring. Thus, the objective of the present systematic review will be to describe the prevalence of copper, selenium and zinc deficiencies in women of childbearing age.

Methods and analysis The search will be performed by independent reviewers. The bases used will be PubMed/MEDLINE, Science direct, Lilacs, Adolec, Scopus, EMBASE, CINAHL, Web of Science, CENTRAL, IMSEAR, PAHOS, WPRIM, IMEMR, AIM for grey literature OpenGrey and OVID. National data will be searched in BDTD. A first search will be performed and a second search will be performed just before submission. Risk of bias assessment will be performed using the Joanna Briggs group prevalence study checklist. Combinable studies will be performed meta-analysis. Heterogeneity will be tested using Cochran's Q test and quantified by the inconsistency test (I^2). In the presence of high heterogeneity, meta-analysis will be performed using the random effects model with Stata metaprop. Summary prevalence will be generated for each outcome, presented in Forest plot figures.

Ethics and dissemination This systematic review will be solely based on published and retrievable literature, no ethics approval will be obtained. Our dissemination strategy will involve the presentation in scientific meetings, as well as the publication of article(s), posters and presentations in congresses.

PROSPERO Registration number CRD42020165352.

Keywords: Women, Fertility, Copper, Selenium, Zinc, systematic review, meta-analysis

Strengths and limitations of this study:

- First systematic review that will assess the prevalence of copper, selenium and zinc deficiencies in women of childbearing age worldwide.
- A thorough and highly sensitive search strategy in leading databases, with no geographic or language restrictions, will be conducted by a multidisciplinary team with experience in systematic review.
- Different cut-off points.

- Heterogeneity among studies.

For peer review only

BACKGROUND:

Micronutrient deficiencies are common in many developing countries and are usually related to inadequate food intake, poor diet quality, low bioavailability (due to the presence of inhibitors, preparation mode and interactions) and/or the presence of infections, and are of growing public health concern^{1,2}. Although the focus of discussions on micronutrient deficiency is around three main problems-vitamin A deficiency (VAD), iodine deficiency disorders (IDD), and iron deficiency anemia (IDA)-with higher prevalences in low-income settings, zinc, selenium, and copper deficiencies have stood out as a cause for concern worldwide, regardless of socioeconomic status^{2,3}. Copper, selenium and zinc are essential minerals in several enzymatic reactions and their deficiencies may be associated with worse prognosis in pregnancy. Deficiencies may increase the risk of premature labor. But there are still contradictions⁴⁻⁶.

Considering women of childbearing age, the consequences of deficiencies of these micronutrients can affect not only these individuals, but also their offspring. These women are susceptible to maternal and fetal deficiencies, affecting future generations⁷. The developmental period in utero is critical for the health of the child, both at birth and long after. Micronutrient deficiencies in women of childbearing age can be exacerbated during pregnancy, increasing the risk of maternal and child complications². Maternal exposure to environmental hazards during pregnancy can therefore have a major impact on child health⁸.

Thus, knowing the global, regional, and national prevalence of these nutritional deficiencies and their social determinants is of fundamental importance for planning policies and programs aimed at women's health in order to reduce the incidence of diseases associated with micronutrient deficiencies, as well as possible negative outcomes in pregnant women and infants.

Question formulation: What is the prevalence of copper, selenium and zinc deficiencies in women of childbearing age?

METHODS AND ANALYSIS

Search strategy

This is the protocol of a systematic review with meta-analysis to identify the global, regional and national prevalence of zinc, selenium and copper deficiencies in women of childbearing age. The study will be developed based on the recommendations of the JBI Manual for Evidence Synthesis⁹ and written based on PRISMA-P (Preferred Reporting Items for

Systematic Reviews and Meta-Analyses Protocol)¹⁰ and the protocol has been registered in the International Prospective Register of Systematic Reviews (PROSPERO)¹¹.

The search will be performed by two independent reviewers (T.C.C and J.C.D.P) and a third reviewer (P.R.F.C.) will be consulted in case of disagreement. The controlled terms will be searched on the MeSH, Decs and ENTREE platforms. The search will be done in PubMed/MEDLINE, Science direct, LILACS, ADOLEC, Scopus, EMBASE, CINAHL, Web of Science, Cochrane Central Register of Controlled Trials (CENTRAL), Index Medicus for the South-East Asia Region (IMSEAR), Pan American Health Organization (PAHOS), Index Medicus for the Western Pacific (WPRIM), Index Medicus of the Eastern Mediterranean (IMEMR) and African Index Medicus (AIM). In order to saturate the searches, manual searches will be conducted with analysis of reference lists of included articles and relevant reviews, contact with authors of included studies, study registries and grey literature in OpenGrey and OVID platforms. For national data approach, results of CAPES theses and dissertations and the Digital Library of Theses and Dissertations (BDTD) will be searched. A first search will be performed and a second search will be performed just before submission.

Inclusion criteria for study designs

Observational cohort or cross-sectional studies and intervention studies with data on micronutrient deficiency before the intervention and with women of childbearing age as the population group will be included. Although most studies consider fertile age 15 to 49 years^{12–14}. In this study, this group will be 10 and 49 years old, by request of the Brazilian Ministry of Health.

Studies in which participants were supplemented with micronutrients (copper, selenium, and zinc) or studies in which participants were selected because they belonged to a group with chronic or high-risk diseases will be excluded. Due to inability to calculate prevalence, case-control articles will also be excluded. Review studies and case reports, in vitro and in vivo studies, book chapters, and any other studies that did not assess prevalence or provide data for possible calculations will also be excluded. There will be no limitations related to language or year of publication, and no search filters will be used.

Qualitative and quantitative studies will be searched, with no date limits, language of publication, or search filter. Search strategies will be developed by a Health Sciences Librarian with experience in systematic reviews. Every strategy will be developed with input from the project. An outline of the search strategy for all bases is provided in the supplementary file.

Study selection

The entire search process will be exported to the Rayyan software (Rayyan QCRI/ web app), initiating the screening stage. Duplicate publications will be excluded to reduce the risk of bias. After this step, we will start reading the title and abstract to select the eligible publications (step I). Studies meeting the criteria will be directed to full-text reading (step II); if necessary, reviewers will contact study authors to obtain additional information to help make the decision about study inclusion in the review. After reading the full text, only studies that meet the pre-established eligibility criteria will be selected. All these steps will be performed by two independent reviewers (T.C.C. and J.C.D.P.) and a third reviewer (P.R.F.C.) will be consulted in case of disagreement.

A flowchart will be prepared accounting for the total number of articles found in the search, selected for screening, eligible for reading in full, included and excluded from the review. After reading in full, all articles that do not meet the eligibility criteria will be excluded and the reasons for this decision will be reported in a spreadsheet to compose the flowchart of study selection. In the manual search, the reference lists of the included articles will be examined, as well as the reviews on the topic, and the team will decide together which studies will be selected for synthesis and data extraction.

Data extraction and data items

After reading and selecting the included articles, data synthesis and extraction will begin. The entire process will be documented in Microsoft Excel software. The information collected will be study identification, study characteristics, participant characteristics, diagnosis and classification of the condition, prevalence, incidence and factors associated with the condition, as presented in table 1.

Table 1 - Information collection

Identification of the study	Title, first author's last name, year of publication, journal, volume, number and pages.
Study characteristics	Participant recruitment period, country, region, study design, study site, study

	setting, sampling process, data collection time, sample size.
Participant Characteristics	Information on study inclusion and exclusion criteria, mean/median age, ethnicity, proportion of participants with any therapy.
Diagnosis and classification of the condition	Measurement or diagnostic criteria used to define the condition (micronutrient deficiency), micronutrient evaluated, unit of measurement, cut-off point adopted.
Prevalence and incidence	Number of participants, total person follow-up time, number of cases of the condition, reported etiologies, prevalence, incidence rate, and their respective confidence intervals and/or p-value.

In the absence of necessary information, the team will contact the authors of the study (maximum of three attempts by e-mail), and the entire process will be documented and logged. The identification of duplicate, overlapping, or complementary articles (multiple articles from the same study) will be performed by identifying the registration numbers of the clinical trials, the authors' names, the city and location of the study (institutions, schools, hospitals, etc.), specific details of the study methodology, date and duration of the study (when applicable). If questions remain, the authors of the articles will be contacted.

Every extraction step will be performed by two previously trained reviewers. Legends will be elaborated with the objective of simplifying the data extraction spreadsheet.

Outcome assessment

The main outcome of this review is the identification of the global, regional (by continent) and national prevalence of zinc, selenium and copper deficiencies in women of childbearing age. These results can serve as a reference for the production of other works in the area, besides making public relevant data on women's health worldwide, supporting citations of this content by other

authors, thus increasing the visibility of scientific production and contributing to the knowledge about the deficiency of these micronutrients in the target audience.

Risk of bias assessment strategy

The evaluation of the risk of bias will be performed using the critical appraisal checklist for prevalence studies⁹. This checklist contains 9 items of questions regarding the sample, data collection, and statistical procedures used in the study. The response options are "yes", "no", "unclear" or "not applicable". The Newcastle-Ottawa scale will be used to evaluate the methodological quality¹⁵.

All studies, regardless of their quality score, will be included in this review and the sensitivity analysis will assess the relevance of methodological quality in the final result. Both steps will be performed independently by two experienced and trained reviewers, and in case of disagreement a third reviewer will break the tie.

Analysis, data synthesis, publication bias and reporting

From these extracted data, a qualitative synthesis will be carried out structured around the prevalence of the deficiencies/inabilities identified in the studies, measurement units and cutoff points adopted, evaluating these results by country and socioeconomic situation (low, lower-middle, upper-middle, and high income countries).

For combinatorial studies¹⁶, quantitative synthesis of data will be performed using meta-analysis. The extent of heterogeneity of the meta-analysis will be tested using Cochran's Q test and quantified by the inconsistency test (I^2 statistic). This statistic determines the magnitude of heterogeneity by the proportion of the total variation between studies due to heterogeneity¹⁶. A p-value is often cited as an indication of the extent of variability between studies. Therefore, the chi-square test will be employed to assess the significance of heterogeneity. A significance level of p-value <0.10 will be used to detect true heterogeneity among study results¹⁶.

The magnitude of heterogeneity will be identified by calculating I^2 , which ranges from 0 to 100%. Thus, I^2 close to zero suggests that all the dispersion can be attributed to the random error of the study, i.e., there is no heterogeneity. If an I^2 value close to 25% is calculated, it indicates low heterogeneity among studies; higher than 50% indicates moderate heterogeneity; and, above 75%, high heterogeneity¹⁶.

In the presence of high heterogeneity, meta-analysis will be performed using the random effects model conducted with Stata's metaprop command. It allows the computation of 95% confidence intervals using the score statistic and the exact binomial method, as well as incorporating FreemanTukey's double-sine-arc transformation of proportions. This method also allows you to model intra-study variability using the binomial distribution. That is, it makes the data distribution normal and stabilizes variances¹⁷. The inverse function of the double sine-arc transformation has also been derived in the literature to recover the original proportion scale after data aggregation¹⁷ while maintaining the interpretability of the final result. Thus, we will generate the summary prevalence for each outcome, as well as its respective 95% confidence interval, presented in Forest plot figures.

Potential variables that may influence the high heterogeneity among studies will be investigated by means of subgroup analysis (for dichotomous variables: age group, ethnicity, socioeconomic status, dosage form [blood or serum], cutoff point adopted, and anthropometric status) and meta-regression (for continuous variables: mean age, sample size, and mean BMI).

If ten or more studies are included in the meta-analysis, Egger's test and the funnel plot will be adopted to assess publication bias. In the funnel plot, the graphic funnel shape makes a qualitative assessment of the possibility of bias, in which asymmetries indicate the presence of publication bias. Egger's test will be applied when the variables are dichotomous or when the distribution of effects is normal (continuous variables); otherwise (asymmetric distribution), Begg's test will be applied. A strong probability that the distribution is not by chance, i.e., presence of publication bias, is suggested when p value <0.05¹⁶.

Ethics, dissemination data protection

Ethical approval was not obtained since the data to be collected and analyzed cannot be linked to specific individuals.

Patient and public involvement

Since this will be a systematic review, there will be no direct patient or public involvement.

Ethics and dissemination

This systematic review will allow the identification of the prevalence of copper, selenium and zinc deficiencies in women of childbearing age at the global, regional and national (Brazil)

levels and will serve as a reference for the production of other works in the area, besides making public relevant data on women's health in Brazil and in the world, supporting citations of this content by other authors, thus increasing the visibility of the national scientific production and the Brazilian contribution to the world scientific knowledge.

Our dissemination strategy will involve the presentation in scientific meetings, as well as the publication of article(s) in international journals, peer-reviewed and open access, preparation of posters and oral presentations in Congresses and scientific events at national and international level, in the areas of nutrition and public health.

Acknowledgements

We would like to thank the whole NUBASE team for all the support in the elaboration of this project.

Contributions: P.R.C.F. supervised the study and contributed to study conception, design, and manuscript drafting. T.C.C contributed to study conception, design, and manuscript drafting. J.C.D.P. contributed to study conception, design, and manuscript drafting. M.L.P.S contributed to study conception, design, and manuscript drafting. S.K. contributed to study conception, design, and manuscript drafting. L.P contributed to study conception, design, and manuscript drafting. All authors critically reviewed and approved the final manuscript for submission.

Funding: This work was supported by the research promotion foundation CNPq, Call MS-SCTIE-Decit/CNPq N° 26/2019 - Research in Food and Nutrition. Funders are not directly involved in project.

Competing interests: This research has no conflict of interest.

Patient consent for publication: Not required.

Reporting checklist for protocol of a systematic review and meta analysis.

Based on the PRISMA-P guidelines.

Instructions to authors

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the PRISMA-Preorting guidelines, and cite them as:

Moher D, Shamseer L, Clarke M, Gherzi D, Liberati A, Petticrew M, Shekelle P, Stewart LA. Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols (PRISMA-P) 2015 statement. Syst Rev. 2015;4(1):1.

			Page
Reporting Item			Number
Title			
Identification	#1a	Identify the report as a protocol of a systematic review	1
Update	#1b	If the protocol is for an update of a previous systematic review, identify as such	1
Registration			
	#2	If registered, provide the name of the registry (such as PROSPERO) and registration number	2
Authors			
Contact	#3a	Provide name, institutional affiliation, e-mail address of all protocol authors; provide physical mailing address of corresponding author	1

Contribution	#3b	Describe contributions of protocol authors and identify the guarantor of the review	10
Amendments			
	#4	If the protocol represents an amendment of a previously completed or published protocol, identify as such and list changes; otherwise, state plan for documenting important protocol amendments	n/a
Support			
Sources	#5a	Indicate sources of financial or other support for the review	10
Sponsor	#5b	Provide name for the review funder and / or sponsor	10
Role of sponsor or funder	#5c	Describe roles of funder(s), sponsor(s), and / or institution(s), if any, in developing the protocol	10
Introduction			
Rationale	#6	Describe the rationale for the review in the context of what is already known	4
Objectives	#7	Provide an explicit statement of the question(s) the review will address with reference to participants, interventions, comparators, and outcomes (PICO)	4
Methods			
Eligibility criteria	#8	Specify the study characteristics (such as PICO, study design, setting, time frame) and report characteristics (such as years considered, language, publication status) to be used as criteria for eligibility for the review	4-5
Information sources	#9	Describe all intended information sources (such as electronic databases, contact with study authors, trial registers or other grey literature sources) with planned dates of coverage	5
Search strategy	#10	Present draft of search strategy to be used for at least one electronic database, including planned limits, such that it could be repeated	5

Page 19 of 20		BMJ Open		
1	Study records -	#11a	Describe the mechanism(s) that will be used to manage	6
2	data management		records and data throughout the review	
3				
4	Study records -	#11b	State the process that will be used for selecting studies	6-7
5	selection process		(such as two independent reviewers) through each phase	
6			of the review (that is, screening, eligibility and inclusion in	
7			meta-analysis)	
8				
9				
10				
11	Study records -	#11c	Describe planned method of extracting data from reports	6-7
12	data collection		(such as piloting forms, done independently, in duplicate),	
13	process		any processes for obtaining and confirming data from	
14			investigators	
15				
16				
17	Data items	#12	List and define all variables for which data will be sought	6-7
18			(such as PICO items, funding sources), any pre-planned	
19			data assumptions and simplifications	
20				
21				
22				
23	Outcomes and	#13	List and define all outcomes for which data will be sought,	6-7
24	prioritization		including prioritization of main and additional outcomes,	
25			with rationale	
26				
27				
28				
29	Risk of bias in	#14	Describe anticipated methods for assessing risk of bias of	8
30	individual studies		individual studies, including whether this will be done at the	
31			outcome or study level, or both; state how this information	
32			will be used in data synthesis	
33				
34				
35				
36	Data synthesis	#15a	Describe criteria under which study data will be	8
37			quantitatively synthesised	
38				
39				
40	Data synthesis	#15b	If data are appropriate for quantitative synthesis, describe	8
41			planned summary measures, methods of handling data and	
42			methods of combining data from studies, including any	
43			planned exploration of consistency (such as I ² , Kendall's τ)	
44				
45				
46	Data synthesis	#15c	Describe any proposed additional analyses (such as	9
47			sensitivity or subgroup analyses, meta-regression)	
48				
49				
50	Data synthesis	#15d	If quantitative synthesis is not appropriate, describe the	9
51			type of summary planned	
52				
53				
54	Meta-bias(es)	#16	Specify any planned assessment of meta-bias(es) (such as	9
55			publication bias across studies, selective reporting within	
56			studies)	
57				
58				
59				
60				

Confidence in [#17](#) Describe how the strength of the body of evidence will be assessed (such as GRADE) n/a
cumulative
evidence
