ABSTRACT

Objectives: Pharmacy assistants are often the first point of contact for patients presenting in community pharmacies. The current role of pharmacy assistants in the supply of asthma-reliever medications (short-acting β-agonists) was identified as a barrier to appropriate guideline-based care. The aim of this research was to devise and evaluate a team-based intervention to formalise the role of pharmacy assistants and to improve asthma guideline-based care in community pharmacy.

Design: A controlled pre-post intervention study was conducted in 336 metropolitan pharmacies located in Perth, Western Australia. Pharmacies were stratified into 2 groups (187 intervention and 149 control) based on known confounders for asthma control. The intervention was designed using a common-sense approach and resources developed included a checklist, videos and web page. Delivery was via workshops (25 pharmacies) or academic detailing (162 pharmacies). Pharmacy practice was assessed preintervention and postintervention via covert simulated patient methodology. Primary outcome measures included patient medical referral, device use demonstration and counselling, internal referral and/or direct involvement of a pharmacist in consultations.

Results: There was a significant increase in patient medical referral in intervention pharmacies from 32% to 47% (p=0.0007) from preintervention to postintervention, while control pharmacies showed a non-significant decrease from 50% to 44% (p=0.22). Device counselling was not routinely carried out at any stage or in any cohort of this research and no significant changes in internal referral were observed.

Conclusions: Increases in medical referral indicate that asthma guideline compliance can be improved in community pharmacy if implementation employs a team-based approach and involves pharmacy assistants. However, results were variable and the intervention did not improve practice related to device counselling or internal referral/pharmacist involvement. Undertaking more workshops may have improved results. Guideline implementation in community pharmacy should consider the role of pharmacy

Strengths and limitations of this study

- This research used a thorough methodological approach to designing a 'common-sense' intervention to improve asthma guideline compliance.
- The intervention was atypical because it recognised the impact of pharmacy assistants on the professional practice of community pharmacists, which is often not considered, but is pivotal, in this setting.
- The intervention was unique in its team-based approach to community pharmacy practice to improve guideline compliance.
- Conclusions were limited by the lack of baseline equivalence of groups for the primary outcome of medical referral.
- Generalisability of the findings was reduced due to self-selection of workshop pharmacies. Self-selection can introduce bias, as participants are likely to be more motivated to improve professional practice.

assistants and how to overcome logistical barriers to pharmacy participation in implementation activities.

BACKGROUND

Asthma is a chronic respiratory disease characterised by recurrent episodes of wheezing, breathlessness, chest tightness and coughing. Although there is no cure for asthma, symptom control can be achieved in most patients with appropriate treatment.[1] However, poor asthma control and inappropriate patient self-management remain an issue in Australia and throughout the world, despite the availability of effective therapies.[2–6]

In Australia, a national classification system exists, called scheduling, which controls how medicines and chemicals are made available to the public.[7] Schedules include S4 'Prescription Only', S3 'Pharmacist Only'

and S2 'Pharmacy Only'. Asthma-reliever medications (short-acting β-agonists or SABAs) are classified as S3 and thus can be purchased without a prescription and without seeing a doctor, but under the direct supervision of a pharmacist.[7] The community pharmacist is required to intervene and refer patients who may be inappropriately managing their condition. The term 'medical referral' is used to denote when community pharmacy staff instruct a patient to seek medical advice from a general practitioner (also called a physician or doctor). Research by Schneider et al[8] demonstrated that community pharmacists were not adequately fulfilling their role in appropriate referral. In response to the identified practice deficits, the Guidelines for provision of a *Pharmacist Only* medicine: short acting beta agonists (SABA guidelines) were endorsed by stakeholders and distributed to pharmacists by the Pharmaceutical Society of Australia (PSA) and The National Asthma Council of Australia (NAC) in 2011.[9]

In recent years, there has been a proliferation of clinical guidelines as a method to promote evidence-based healthcare. However, research suggests that clinicians frequently do not follow guidelines, resulting in an evidence-practice gap.[10 11] In the community pharmacy setting, research on clinical guidelines implementation is relatively new and there is little evidence on how to improve evidence-based practice.[12] Most of the research to date has focused on the potential of pharmacists to achieve positive patient health outcomes through enhanced services delivery.[13 14] While this can indicate some of the issues relevant to suboptimal evidence-based practice, it does not fully explain the barriers to research translation and effecting change on the routine practice of community pharmacists.

The standards accreditation process (Quality Care Pharmacy Program) for community pharmacies in Australia requires pharmacy assistants, involved in handling non-prescription, scheduled medicine sales (including SABAs), to complete an online training unit by the Pharmacy Guild of Australia, while under supervision in the workplace.[15 16] Pharmacy assistants not working in accredited pharmacies and/or not servicing patients with non-prescription, scheduled medicines are not required to complete the Guild courses and may not receive any formalised training. However, with 90% of pharmacies across Australia currently accredited[17] the majority of pharmacy assistants should receive some basic training.

Focus groups conducted with pharmacists and pharmacy assistants in 2012, regarding the utility of the SABA guidelines, indicated that there were many barriers to guideline-based practice.[18] Particularly remarkable was the observation that pharmacy assistants who participated in the study were universally unaware of the guidelines, but were highly involved in the non-prescription supply of SABAs, rather than internally referring patients to the pharmacist.[18] This lack of knowledge and high participation in supply was unexpected because of the mandatory training requirements for pharmacy

assistants (in accredited pharmacies) and the legislation requiring pharmacists to be directly involved in patient assessment and supply of SABAs (S3 'Pharmacist Only' legislation).[15 19 20]

The initial implementation strategy of the SABA guidelines had not addressed the issue of pharmacy assistant involvement and the barriers to internal referral of patients from pharmacy assistants to pharmacists.[21] There was no acknowledgment of the workflows that exist in community pharmacy whereby the pharmacy assistant is often the first person to encounter patients requesting non-prescription asthma-reliever medications. There was only recognition of the legislation requiring pharmacist involvement; thus, the focus was to disseminate information about the guidelines to pharmacists.[21] The focus group observations indicated that this was a significant oversight, particularly in light of previous research by Schneider et al.[8 22] Schneider et al[8 22] ascertained that outcomes for asthma patients, in terms of appropriate medical referral, were poorer when pharmacy assistants alone were involved in asthma-reliever medication sales.

Another barrier identified in non-prescription SABA supply was the difficulties pharmacy assistants encountered trying to engage with asthma patients, who they found resistant to questioning and impatient.[18] Research shows that there is discordance between perceived asthma control and actual symptomatic control,[23–26] so it is not unexpected that patients with asthma are resistant to engagement: they do not perceive they need support. Unfortunately, poor patient disclosure of health information in community pharmacy is an issue, which can influence appropriateness of outcomes.[27 28] Where such barriers exist, the recommendation is for interventions that promote better communication between patients and pharmacy staff.[27]

It was evident that workflows supporting the involvement of pharmacy assistants, unaware of the SABA guidelines and experiencing difficulties with engagement of patients with asthma, were creating a barrier to pharmacist participation, appropriate guideline-based assessment and patient medical referral. Therefore, the aim of this research was to devise and evaluate a team-based intervention to formalise the role of pharmacy assistants in order to improve asthma guideline-based care in community pharmacy.

METHODS
Design of a 'common-sense' intervention to overcome an identified barrier

'Common-sense' interventions are designed using a pragmatic and logical approach based on empiric evidence and past experience.[29] The design of this intervention was undertaken by researchers with experience and knowledge of community pharmacy practice, based on evidence obtained from the scientific literature and information from focus groups. Researchers, from their

experience in community pharmacy, recognised that activities undertaken in the pharmacy required team effort and team support. Evidence from the literature was gleaned by undertaking a systematic review to examine the effectiveness of implementation strategies for clinical guidelines to community pharmacy.[12] There was little evidence that was conclusive about the best approach to implementation of guidelines in community pharmacy, but there was an observation that it was important to consider the role of non-professional staff (pharmacy assistants), due to the influence they can have on the practice of pharmacists. This observation is consistent with the findings of Schneider et al[22] who demonstrated improved patient outcomes associated with patient referral from assistants to pharmacists. However, few implementation interventions had previously included pharmacy assistants. Also there were few studies based on and demonstrating the benefit of behavioural theory in intervention design. Reviews on guideline implementation from other settings were also considered and there was a general consensus that it was important to identify barriers and tailor interventions to overcome them.[30 31] Focus groups were used to map barriers and facilitators of guideline implementation and asthma management.[18] Many barriers were identified, but two key issues were used in developing the intervention. Communication issues were problematic due to the discordant views of patients and health professionals on asthma management. It was also evident from the focus group discussions that pharmacy assistants played a significant role in assessing and counselling patients but had problems engaging with patients. A variety of intervention options were considered, including smartphone apps, legislative changes and patient health promotional activities. Ultimately formalising an appropriate role for pharmacy assistants to support pharmacists was chosen. This option was practical, relatively simple, unique and supported by the evidence and preliminary research.

Design logistics

Small group workshops were chosen as the delivery mode for the 'common-sense' intervention. Poor uptake of workshop invitations required adaptation of the intervention and subsequently academic detailing was undertaken in pharmacies in the intervention group that did not participate in workshops. Academic detailing was a reasonable adaptation based on evidence of effectiveness of this strategy from the literature,[32 33] and the fact that it uses face-to-face interaction in the practice setting, as did the workshops. Workshops and academic detailing were completed between October 2013 and March 2014.

The primary author (KW) conducted the workshops. As a community pharmacist and pharmacy proprietor, the primary author had a good understanding of the workshop material and of pharmacy staff and their working environment. A background of teaching pharmacy practice and communication skills provided the

necessary skillset to conduct workshops. Workshops were conducted in each pharmacy and all staff members of that pharmacy were encouraged to participate. Workshops ran for between 1 and 2 hours depending on the level of group discussion. Conducting training in-store allowed for tailoring of information based on the observed environment, current workflows and staff relating previous experiences with patient engagement. The components of the intervention included group education and communication skills training. Information was provided about asthma, the patient perspective, improving communication, legislative requirements, the SABA guidelines and remuneration opportunities in practice. A Microsoft Power-Point presentation, two videos and checklist tool were developed specifically for the workshop. Educational materials from the NAC and Asthma Foundation of Western Australia, as well as copies of the SABA guidelines from the PSA, were provided to pharmacies.

Workshops were interactive and group discussion was used to motivate staff and give them 'ownership' of the optimum way to use the resources. It was important to include pharmacists in the intervention and not just pharmacy assistants. During the intervention design process, recognition was given to the fact that the community pharmacy functions as a whole system and pharmacy assistants and pharmacists needed to support each other to achieve the desired outcomes. To maintain practice-change post workshop, pharmacies were provided a DVD of all workshop content (including the video material), notepads of checklists ready to implement and a link to a web page containing PDF documents of the guidelines and checklist that could be printed (http://www.asthma-pharmacy.org). They were also encouraged to contact the research team if they had any issues or successes.

Academic detailing is also known as educational outreach. It involves trained researchers visiting health professionals in the workplace to provide them information on how to change practice. Three pharmacists were trained by the primary author (KW) to conduct detailing visits. Each academic detailing visit took ~15 min. The trained academic detailers were given a standardised protocol to ensure uniformity in the information provided to the community pharmacies. The information and resources provided in the academic detailing visits were consistent with the information provided in the workshop. The difference was that the information was provided to the pharmacist-in-charge at the time of the visit, rather than the pharmacy staff as a team. This required the pharmacist-in-charge to act as a disseminator of information and driver of practice change. It also did not allow for tailoring of the information via group discussion as was achieved in workshops. Pharmacies received, as part of the academic detailing visit, a copy of the SABA guidelines, a DVD of all workshop content (including the video material), notepads of checklists ready to implement and a link to the asthma-pharmacy web page (http://www.asthma-pharmacy.org).

Resources

Checklist development

A tool was devised centred on the assessment information outlined in the SABA guidelines (see online supplementary material). The concept was based on an existing Emergency Contraception checklist[34] that is accepted and widely used by pharmacies in Western Australia.[35] It was anticipated that an equivalent tool for provision of SABAs would be relatively easy to incorporate into practice. The Asthma Medication Request Checklist is a 7-item simple tick-box tool, which can be completed by patients alone or with the support of a *pharmacy assistant*, within a couple of minutes.

It aimed to influence all of the target outcomes by acting as a prescreening tool, an internal referral tool and time-management tool. An incentive to using the checklist was that it complied with documentation requirements to access remuneration pathways for clinical service provision and meet accreditation standards. An expert panel of pharmacists was used to refine the tool and it was formatted in a way consistent with other tools promoted by PSA. As a communication tool/patient engagement tool, the checklist allowed pharmacy assistants to collect information from patients not receptive to answering questions. It achieved this in a few ways. The form added formality to the interaction making patients feel that it was important to answer the questions. It overcame patient frustration with the inadequate communication skills of pharmacy assistants. Pharmacy assistants were empowered to collect information where previously they had been reluctant to ask questions for fear of 'upsetting patients'. It also avoided a situation whereby patients were asked the same questions by assistants and then again by pharmacists. Collecting the information was time effective, which was important in situations where impatience was undermining interactions. It also allowed pharmacists to have more in-depth and personalised discussions based on the information already gathered. Such tailored conversations were more relevant, meaningful and interesting to patients. The checklist was an alternative way of engaging with patients who had become accustomed to pharmacy staff asking 'annoying' questions in an unimaginative way, or not making any assessments at all. Staff were reminded that filling in the checklist was not the goal. The checklist was simply a tool to help them engage and achieve appropriate guideline-based care of the patient.

Training videos

Two videos were produced for the training workshops. The first video was a patient story describing a near death experience with asthma. It not only served to provide information to workshop participants about health consequences of asthma but also provided insight into patient behaviours and attitudes that may undermine their health. The patient story assisted in persuading pharmacy staff (assistants and pharmacists) to persevere with tackling the issue of asthma. Understanding the patient perspective was also used as a method of enhancing communication and a more empathic approach by pharmacy staff. The second video was a role-play video used to demonstrate the difficulties with patient engagement and also to model the desired behaviour and use of resources. Humour in the videos was used to facilitate discussion. By sharing stories of problematic patient encounters, staff were able to reflect on how to improve patient engagement in the future.

Trial design

The study was a controlled trial with a control group (no intervention) and an intervention group conducted in community pharmacies in Perth, Western Australia. The groupings were based on geographical location. Perth is an urban centre with development extending along the coastline of the Indian Ocean and divided by the Swan River. To the east of the city is a steep escarpment known as the Darling Scarp. The areas chosen were the south and north metropolitan areas of Perth, Western Australia. Eastern suburbs were excluded due to possibility of environmental and socioeconomic factors influencing results, as indicated by a report on geographic distribution of asthma hospitalisations from Australia.[36] The purpose of the stratification was to reduce potential cross-contamination of data using the Swan River as a geographical barrier. A randomised, prebaseline, pilot assessment was used to demonstrate that the selected north/south groups were equivalent. Assessments were performed at baseline and postintervention. The study was performed between September 2012 and June 2014. The sample size was determined by including all pharmacies in the south and north Metropolitan area of Perth, Western Australia, listed on the Pharmacy Registration Board of Western Australia Premises Register.[37] Hospital pharmacies were excluded from the study. The primary author performed all group allocations.

Prebaseline pilot testing

Simulated shoppers visited a random sample of 60 pharmacies in the non-intervention and intervention groups (30 south and 30 north) in September 2012. This pilot testing was undertaken before baseline data collection started, to validate the stratification method chosen. There were no significant differences in the cohorts for the primary outcome of appropriate medical referral (63.3% referral south vs 56.7% referral north, p=0.60).

Implementation of the intervention

Each community pharmacy in the intervention area (north metropolitan) was invited to participate in an individual, in-store, small group, asthma-training workshop. An initial invitation letter was sent with follow-up via phone call and email. The invitation encouraged all pharmacy staff to attend, including professional and non-professional staff; full-time, part-time and casual staff. The primary author enrolled all workshop

participants. Academic detailing of workshop content was provided to pharmacies in the intervention area that did not participate in workshops. Academic detailing was performed using a 'cold calling' method with no prior appointment. This method was selected after consultation with researchers with previous experience in academic detailing in community pharmacy. With visits being conducted during normal working hours, interruptions to conversations were inevitable. To minimise the disruptions, detailing visits were scheduled between 10:00 and 16:00. Detailers were limited to a maximum of eight detailing visits in 1 day to avoid fatigue.

Data collection

Data collection was via covert simulated patient methodology. As per ethics approval, pharmacies were not informed that they would receive simulated patient visits. This methodology has been widely and successfully used in the community pharmacy setting by pharmacy practice researchers at the Centre for Optimisation of Medicines at the University of Western Australia.[8 22 38–40]

A 1-day training session was held for four research assistants who were provided information about the scenario, data collection and data entry. The training session provided opportunities for role-play and refinement of tools where necessary. Following the training day, the research assistants piloted the methodology in eight pharmacies to ensure fluency in the scenario and to test for unforeseen issues. The research assistants included a female pharmacist aged 25–30 years, two university students aged 20–25 years (man and woman) and a woman aged 45–50 years. Simulated patients were blinded to the group allocation.

Scenario

The scenario involved a simulated patient presenting to a community pharmacy asking 'Could I buy a Ventolin please?' Ventolin is a common brand of asthma-reliever medication used in Australia. Although the simulated patients could provide more information upon request, they were instructed not to volunteer information. Table 1 outlines the scenario description. If pharmacy staff sought further information, patient assessment would reveal a patient with poorly controlled asthma and poor inhaler technique. This required inhaler technique training and immediate medical referral in accordance with guidelines.[1 9] Simulated patients were provided an empty Ventolin inhaler if asked to demonstrate inhaler technique.

Outcomes

The primary outcomes of interest related to guideline and legislative compliance. These included patient medical referral to a doctor for uncontrolled asthma, inhaler device demonstration and increases in pharmacy assistant to pharmacist internal referrals or direct

Table 1 Simulated patient scenario description

Patient request	'Could I buy a Ventolin® please?'	
Possible questions and answers based on WWHAM guidelines	Who is the patient?	'Me'
	What are the symptoms?	'Breathlessness'
	How is your asthma?	'I have been feeling a bit breathless lately'
	How long have you had asthma/symptoms?	'Had asthma for years but getting worse over the last month'
	What treatments have you tried for these symptoms?	'I use Ventolin metered dose inhaler and Seretide metered dose inhaler'
	Do you have any other medical conditions/medications?	'No'
	Do you have any allergies?	'No allergies'
Additional information	Asthma has been getting worse over last month	
	For the last month has been using Ventolin 2 puffs once every day to relieve symptoms	
	Has been using Seretide regularly at a dose of 2 puffs twice a day for 2 years	
	The last time they saw a physician/doctor was 'ages ago'	
	Has not ever been admitted to hospital with asthma before	
	Does not have a written asthma action plan	
	Does not know the 'rule of 4's'—what to do in an emergency	
	Trigger factors for asthma include pet hair and pollen	
	Ventolin=salbutamol 100 μg per actuation (blue inhaler)	
	Seretide=fluticasone/salmeterol 250 μg/25 μg per actuation (purple inhaler)	
Inhaler technique	If inhaler technique is assessed, the inhaler is **not** shaken before use and the breath is **not** held after inhalation	
Appropriate outcome	A. Medical referral for poor asthma control	
	B. Correction of poor inhaler technique	

WWHAM, Who, What, How long, Action taken, Medication.

involvement of a pharmacist in consultations. Secondary outcomes included use of the Asthma Medication Request Checklist introduced in the intervention and increases in the number of appropriate assessment questions asked by pharmacy staff (pharmacists and pharmacy assistants).

Statistical analysis

Percentages and counts (N) were calculated for each of the categorical variables for the intervention and non-intervention pharmacies at pre-post intervention time points. To investigate whether north and south pharmacies were equivalent, prebaseline χ^2 tests (or Fisher's exact tests where appropriate) were conducted to compare whether specific questions were asked. To investigate bias between simulated patients, a χ^2 test was conducted comparing the primary outcome of patient medical referral. Binary logistic regression was used to investigate differences in whether specific questions were asked (event='Yes') between cohorts (intervention and non-intervention) and times (each model also contained their respective interaction). ORs, 95% CIs and

p values are provided. Linear regression was conducted to analyse differences in continuous outcomes between cohorts and times. Mean differences, SE of the differences and p values are provided. Data were analysed using the R (Version 3.1.3) environment for statistical computing (R Core Team. R: a language and environment for statistical computing, 2015. http://www.r-project.org).

RESULTS
Participant flow

Simulated patient visits were conducted in 336 pharmacies at two time points (preintervention (January 2013–March 2013) and postintervention (April 2014–June 2014)). Of these, 187 pharmacies received an intervention (north metropolitan) and the remaining 149 pharmacies (south metropolitan) did not. Workshop interventions were conducted in 25 pharmacies with 137 staff members. Academic detailing was undertaken in 162 pharmacies. A total of three pharmacies were excluded from the analyses due to incomplete data. Figure 1 shows the flow of participants through the intervention.
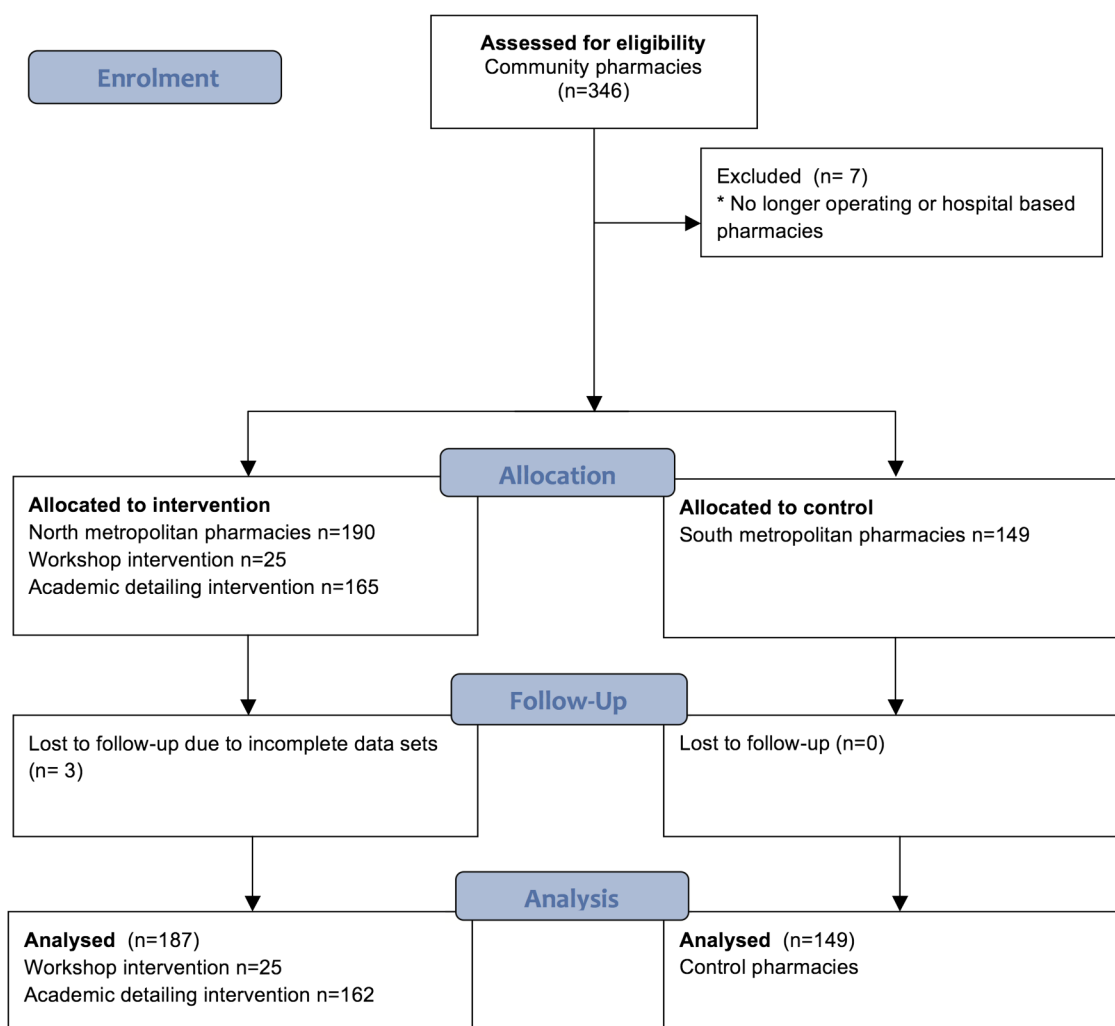

Figure 1 CONSORT flow chart of participants.

'Counsellor' refers to the pharmacy staff member interacting with the patient.
*Each analysis was performed as the individual category versus the rest.
†This analysis was performed as: no waiting time versus waiting time due to limited numbers in the 'over 5 min' category.
NS, not significant; pre, preintervention; post, postintervention.

Simulated patient assessments

Information recorded by simulated shoppers included pharmacy details, counsellor details, consultation details, patient assessment, device use assessment, patient counselling and resource use (eg, Asthma Medication Request Checklist). No bias was detected as a result of differences between simulated patients. There were no observed significant differences for the primary outcome of patient medical referral between simulated patients.

Pharmacy, counsellor and consultation details

Pharmacy demographics were recorded. This included the location (street, medical centre, shopping centre and other) and type (independent or chain) of each pharmacy. The term 'counsellor' refers to the pharmacy staff member interacting with the patient: assessing their needs and/or providing advice. Table 2 outlines the pharmacy, counsellor and consultation characteristics that were assessed. Few of the characteristics were observed to be significantly different over time in either the intervention or non-intervention areas. In both cohorts, at both time points, the position of the counsellor (either pharmacist or assistant) was unclear in almost 50% of simulated patient visits. There were no significant changes to initial pharmacist involvement in consultations. There were also no increases in internal referral, as indicated by a change in counsellor from pharmacy assistant to pharmacist, as a result of the intervention. The intervention and non-intervention cohorts significantly decreased their patient waiting times between the pre and post time points, but there were no significant differences in the decreases in pharmacy busyness between cohorts (intervention and non-intervention).
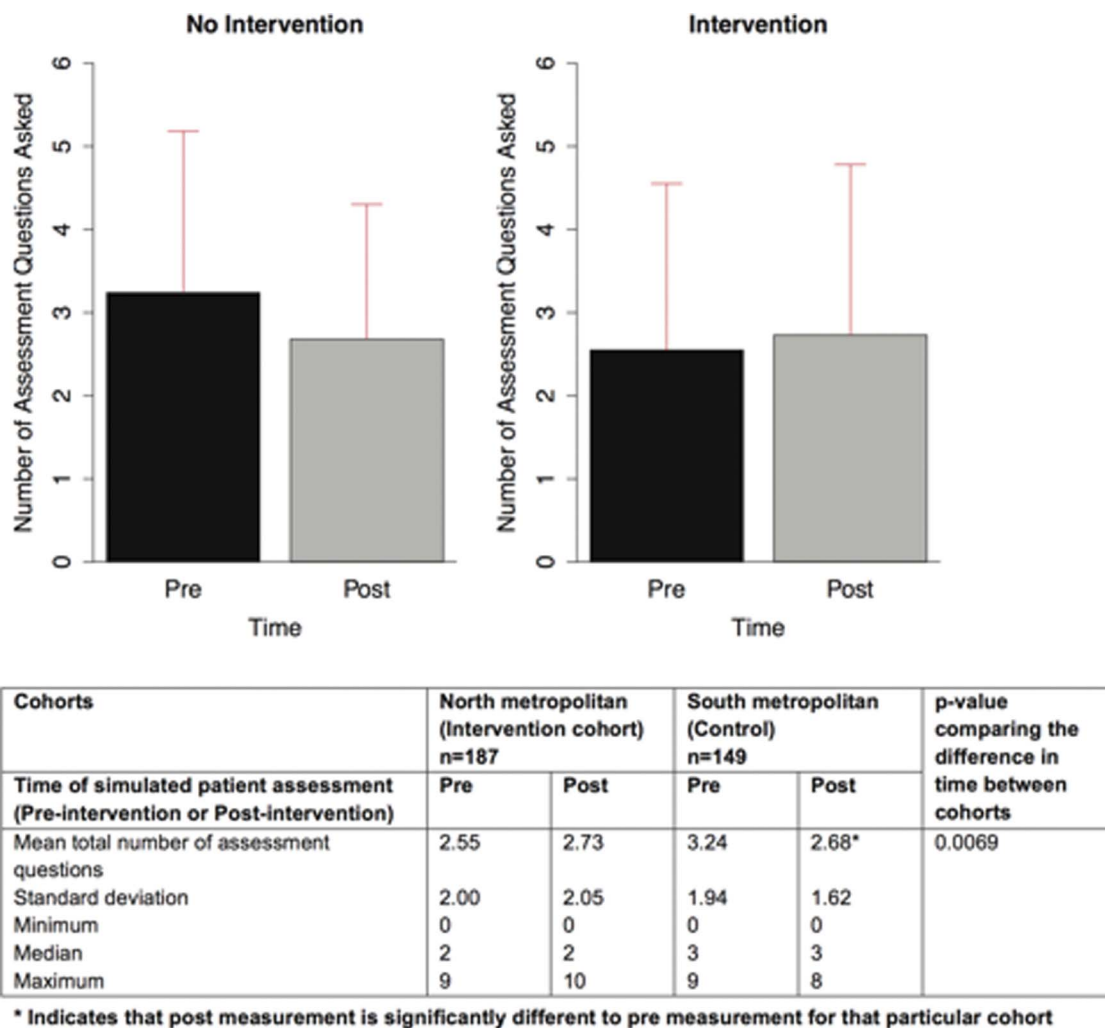

Patient assessment

Table 2 indicates the results of patient assessment by pharmacies. There was little difference in the assessment questions asked between both time points and between pharmacies. One exception was the question about preventer use. Analysis indicated that control and intervention pharmacies were more likely over time to ask about preventer use (post vs pre: OR 5.89, 95% CI 4.11 to 8.45, p<0.0001). The total number of assessment questions asked was significantly related to the intervention and time (p=0.0069). Figure 2 indicates that the mean total number of assessment questions asked at baseline was higher in the control cohort compared to the intervention cohort (mean difference 0.69, SE=0.21, p=0.0012) and this declined over time for the control cohort (mean difference=0.56, SE=0.20, p=0.0062), whereas in the intervention cohort, the mean total number of assessment questions did not significantly change over time (mean difference=0.05, SE=0.21, p=0.82).

Device use and counselling

Device counselling was not routinely carried out at any stage or in any cohort of this research. As indicated in table 2, almost all counselling points recorded were

Cohorts	North metropolitan (Intervention cohort) n=187		South metropolitan (Control) n=149		p-value comparing the difference in time between cohorts

Figure 2 Mean total number of assessment questions asked.

similar at both time points and in all pharmacies. The exceptions were patient medical referral and information provided about medication duration/frequency of use. Non-intervention pharmacies showed a non-significant decrease in patient medical referral from 50% to 44% (p=0.22). In comparison, intervention pharmacies showed a significant increase in patient medical referral from 32% to 47% (p=0.0007). Baseline medical referral was significantly different between cohorts. The non-intervention cohort was significantly more likely to refer at baseline (intervention vs control at time preintervention: OR 0.45, 95% CI 0.29 to 0.71, p=0.0005). Postintervention, there was no significant difference in medical referral between the intervention and control cohort (intervention vs control at postintervention: OR 1.13, 95% CI 0.74 to 1.75, p=0.56). Pharmacies in the intervention cohort were significantly more likely to discuss duration/frequency of reliever medication usage postintervention than preintervention (OR 2.97, 95% CI 1.53 to 5.77, p=0.0013). This was significantly different to the observations in the non-intervention group where discussions about duration/frequency of reliever use in this cohort

remained the same over the two time periods (p=0.0201).

Figure 3 illustrates some of the significant outcomes across the cohorts and over time.

Resource use

Of the 187 pharmacies that received the intervention, 2 pharmacies (1%) used the Asthma Medication Request Checklist introduced. One pharmacy was from the workshop cohort and one pharmacy was from the academic detailing cohort. Correspondence with the primary author indicated that more pharmacies were using the resource, but this was not evident in the simulated shopping results. Two workshop pharmacies sent emails providing feedback about successful patient interactions using the checklist and another workshop pharmacy requested delivery of more checklists to use. None of these pharmacies were noted as using the checklist during simulated patient visits.

DISCUSSION

The aim of this research was to devise and evaluate a team-based intervention to formalise the role of

Figure 3 Outcomes between cohorts and time points.
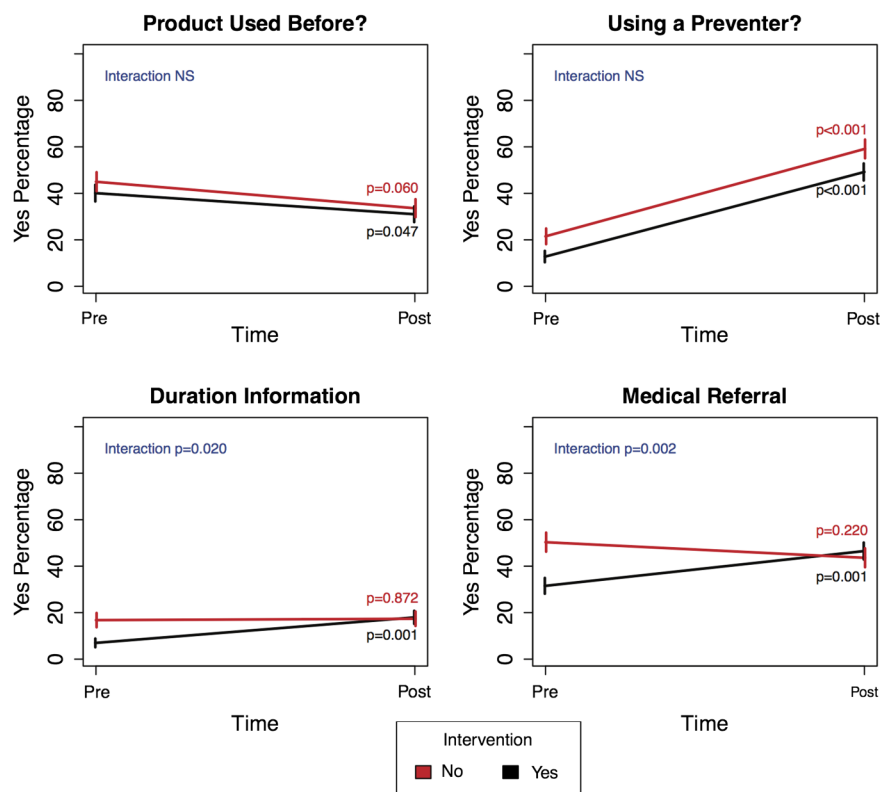

pharmacy assistants in order to improve SABA guideline-based care in community pharmacy.

A key primary outcome of interest was increased patient medical referral due to identification of poor asthma control. The significant increase in medical referral observed in the intervention group indicates the potential effectiveness of this intervention. Another positive outcome observed was the increased incidence of discussions with patients about reliever duration and frequency of use. However, outcomes were variable and these positive results were not supported by results for other primary and secondary outcomes such as internal referral of patients from pharmacy assistants to pharmacists (indicating greater legislative compliance), increased device counselling or use of the 'Asthma Medication Request Checklist' tool.

Some of the variability in the results may have been due to the workshop content and emphasis on particular elements of the guidelines. Inhaler device counselling was not an element of the guidelines specifically addressed in the workshop and only one question in the checklist related to previous device demonstration. In contrast, there was a greater focus on appropriate assessment of asthma control and medical referral criteria. This emphasis was borne out in the results and demonstrates that the content of a workshop can have an influence on outcomes. Furthermore, in this research, one person undertook all workshops, but the flexible, tailored approach could potentially lead to variable outcomes from multiple presenters who provide different emphases in a wider implementation programme. It is

possible that constructing the workshop differently to focus on areas of poor practice related to the guidelines could have achieved better results.

Another reason for the variations in the success of this intervention may lie in the adaptations applied to the intervention during the course of the research.[41] A thorough 'common-sense' approach was used in the design of the intervention. There was recognition, in choosing small group workshops, that community pharmacies are complex healthcare organisations requiring a team approach to implementation of new practice. However, in a naturalistic research setting, there are complexities that cannot always be predicted and controlled. Community pharmacies operate in a retail environment with long hours and are subject to seasonal fluctuations in workload. The workshops were initially offered in October and the poor uptake was attributed to the 'busy Christmas retailing period'. Another issue was the difficulty in holding staff gatherings with extended trading hours and the large number of part-time and casual employees in the retail sector. Holding training outside of working hours also required investment on the part of business owner in terms of wages for staff. All these logistical issues inhibited uptake of the workshop intervention. This necessitated an adaptation of the workshop intervention[41] that could be delivered via academic detailing.

Academic detailing was achievable on a much larger scale, but it did not facilitate team support for the initiative and relied on internal communications within the pharmacy to disseminate information and promote

practice change. It also did not provide the opportunity to tailor the information to individual pharmacies. It is possible that the intervention could have achieved stronger positive outcomes if more workshops had been completed. Unfortunately, this study was not powered to detect a statistically significant difference between the academic detailing and workshop strategies. However, some trends were noticed that suggest the superiority of workshops compared to academic detailing. Both intervention groups were more likely to ask patients about preventer use at the postintervention time point, but there was a greater increase in the odds of this occurring in workshop pharmacies. Also workshop pharmacies asked significantly more assessment questions than academic detailing pharmacies. It is important that future research and intervention design should consider logistical issues to ensure successful implementation of guidelines. There are several taxonomies and frameworks available that may assist and provide a more systematic approach to intervention design and consideration of logistical issues.[42–44]

Despite the logistical problems encountered, the rationale in choosing small group workshops for interventions in community pharmacy seems to have merit, due to acknowledgement of the team-based environment that community pharmacists practice in. It is recognised that team-based change is likely to be slower and more incremental than changing the practice of an individual healthcare practitioner[45] and hence the difficulty in achieving practice change in the community pharmacy setting, regardless of logistical issues. Results indicated some improvements in individual counselling and medical referral but not in system-level process improvements. Improvement in the outcomes of internal referral, device counselling and use of the new checklist necessitates workflow changes and this was not evident. Examples of partial or individual implementation success can be seen in the three pharmacies that either provided qualitative feedback about using the checklists or requested more checklists. Despite these self-reported indications of implementation success, none of the pharmacies were noted as using the checklist tool when visited by a simulated patient.

Historically, translating evidence into practice has been an incredibly slow and unpredictable process and it can take decades for empirical research to be implemented in routine medical practice.[46–48] With practice change being a slower process for teams rather than individuals, it may have been that the dose and duration of this intervention were not substantial enough to achieve strongly significant outcomes and allow time for process adjustments. Reinforcement of the intervention was by way of resources, including access to a web page. Multiple workshops or detailing visits over a longer time frame may have provided stronger reinforcement of messages; opportunities to refine modified workflows and possibly could have improved outcomes. It is recognised that when new behaviours are attempted in the

workplace, but routines are yet to be fully established, reinforcement can play a crucial role in maintenance and entrenchment of new practice.[49] Given the team environment of community pharmacy, a substantial reinforcement programme should be factored into future interventions or guideline implementation initiatives.

Not only was team-based change required for intervention success but the intervention also needed to influence mutual engagement between pharmacy staff and patients. Patient engagement issues were addressed in a number of ways. Strategies such as communication skills training[27 28] and providing insight into the patient perspective[50] were based on evidence from the scientific literature. Other measures included recognition of the problems faced by pharmacy staff and the introduction of the Asthma Medication Request Checklist tool to assist with information gathering. However, it is possible that without an intervention directed specifically at patients, these measures were not sufficient to achieve the required change in patient beliefs and behaviours to achieve mutual engagement and information exchange. The work of Watson et al[27] found that the willingness of patients to provide information to pharmacy assistants was correlated with behavioural intentions and subjective norms. Without addressing the complexities underlying patient behaviour, substantive changes in asthma management may be unachievable. This suggests that there may be benefits in using a behavioural theory-based approach in intervention design, which is increasingly being recommended in the scientific literature.[47 51 52] However, a similar study, using the Theory of Planned Behaviour in intervention design and targeting pharmacy assistants, ultimately did not improve guideline compliance.[28] At present, there is limited evidence of the benefits of the use of theory in the implementation of guidelines, particularly in the community pharmacy setting.[12]

Direct pharmacist involvement and internal referral of patients from pharmacy assistants to pharmacists were considered important measures of legislative compliance. Legislation in Australia requires pharmacists to be directly involved in SABA sales. The results demonstrated no impact on either direct pharmacist involvement or internal referral due to the intervention. However, the large number of simulated patient visits for which the counsellor position could not be identified confounds interpretation of the true incidence of pharmacist involvement in consultations or of internal referral. The practical issue this identifies is that patients do not know whom they are talking to in almost half their visits to a community pharmacy. This situation is not conducive to optimal communication where patients can confidently seek and receive advice from a highly trained health professional: the community pharmacist. While no changes in internal referral were observed, both groups had an increase in the percentage of pharmacy assistants 'consulting' with a pharmacist, and this

increase was significant in the control cohort. Consultation with a pharmacist means that the pharmacy assistant handles the entire patient interaction but refers to the pharmacist for advice or permission to conduct the sale. Such 'consultation' does not meet the requirements for legislative compliance and has been shown to worsen outcomes in previous research.[8] Best outcomes are observed when successful internal referral occurs.[8]

The final significant observation from this research relates to the poor practice surrounding device counselling and demonstration of asthma inhalers. Despite being an inherent component of the SABA guidelines, device counselling was not routinely carried out at any stage or in any cohort of this research. Correct inhaler technique is crucial in optimising asthma treatment and minimising side effects. International guidelines recommend that pharmacists should contribute to patient education about inhalers and this is not occurring.[53] The importance of this area, and the deficits in current practice, warrants specific attention. The results in this study are not unique and deficiencies in patient education on inhaler technique have been observed in other studies.[8 54 55] Therefore, barriers to the provision of this service need further investigation.

CONCLUSION

Increases in medical referral indicate that asthma guideline compliance potentially can be improved in community pharmacy if implementation employs a team-based approach and involves pharmacy assistants, giving them a more defined and formalised role. However, the implementation intervention did not improve practice related to device counselling or internal referral/pharmacist involvement. These variable results may have been improved if more workshops had been undertaken. Logistical barriers to using workshops as an intervention strategy in this setting need to be overcome to test this hypothesis. Future research on guideline implementation to community pharmacy should consider the role of the pharmacy assistant and how to overcome logistical barriers to pharmacy participation in implementation activities. Consideration also needs to be given to the duration of an intervention and incorporation of reinforcement messages.
