ABSTRACT

Objectives To examine whether there are associations between active travel and markers of a healthy, low-carbon diet (increased consumption of fruit and vegetables, reduced consumption of red and processed meat).

Design Cross-sectional analysis of a cohort study.

Settings Population cohort of over 500,000 people recruited from 22 centres across the United Kingdom. Participants aged between 40 and 69 years were recruited between 2006 and 2010.

Participants 412,299 adults with complete data on travel mode use, consumption of fruit and vegetables and red and processed meat, and socio-demographic covariates were included in the analysis.

Exposure measures Mutually exclusive mode or mode combinations of travel for non-work and commuting journeys.

Outcome measures Consumption of fruit and vegetables (FV) measured as portions per day and red and processed meat (RPM) measured as frequency per week.

Results Engaging in all types of active travel was positively associated with higher FV consumption and negatively associated with more frequent RPM consumption. Cycling exclusively or in combination with walking was most strongly associated with increased dietary consumption of FV and reduced consumption of RPM for both non-work and commuting journeys. Overall, the strongest associations were between non-work cycling and FV consumption (males: adjusted odds ratio=2.18, 95% confidence interval=2.06, 2.30; females: 2.50, 2.31, 2.71) and non-work cycling and RPM consumption (males: 0.57, 0.54, 0.60; females: 0.54, 0.50, 0.59). Associations were generally similar for both commuting and non-work travel, and were robust to adjustment with socio-demographic and behavioural factors.

Conclusions There are strong associations between engaging in active travel, particularly cycling, and healthy, low-carbon (HLC) dietary consumption, suggesting that these HLC behaviours are related. Further research is needed to better understand the drivers and dynamics between these behaviours within individuals, and whether they share common underlying causes.

Article summary

Strengths and limitations of this study

- This study uses the UK Biobank to examine associations between active travel and diet in order to better understand the patterning of healthy, low-carbon lifestyles.

- UK Biobank is a large cohort with very rich data, which enabled assessment of relationships using several measures of travel and dietary behaviour and adjustment for a wide range of socio-demographic, environmental, and behavioural covariates.

- The analysis used in this study is cross-sectional and therefore we cannot infer causality between these behaviours.

- This study is further limited by the use of self-reported measures of active travel and dietary consumption.

3

1 **INTRODUCTION**

2 Increasing concerns about global climate change combined with rising rates of chronic disease have

3 led to greater policy attention on behaviours and lifestyles that are beneficial for both human health

4 and the natural environment [1-3]. From this perspective, two priority behaviours that have been

5 identified are engaging in healthy, low-carbon travel (e.g. walking and cycling for transport) and

6 consuming healthy, low-carbon diets (e.g. reduced consumption of meat, increased consumption of

7 fruit and vegetables) [4-8]. Modelling studies have shown that a population shift toward these

8 behaviours would lead to a range of health and environmental co-benefits: increased life

9 expectancies, decreased rates of Type 2 diabetes, cardiovascular diseases and cancer, as well as

10 large reductions in transport and food-related greenhouse gas emissions [3 6 7 9-12]. These shifts are

11 also in line with national health guidelines. In the UK, for example, walking and cycling for transport is

12 widely recommended as a key strategy to increase population physical activity [13 14], and adults are

13 advised to base at least two-thirds of their diet on plant-sourced foods, specifically consuming at least

14 5 portions of fruit and vegetables (FV) and less than 70 grams (g) of red and processed meat (RPM)

15 per day to prevent chronic disease outcomes [15 16]. These dietary principles are also in alignment

16 with the recently published 'planetary health diet' which argues that huge changes in consumption of

17 fruits, vegetables, and red meat are needed on a global scale if we are to stay within safe planetary

18 boundaries [17].

19

20 In the UK, studies that have examined these travel and dietary behaviours at the population level

21 have found that they are strongly patterned by socio-demographic factors [18-22], which suggests that

22 healthy, low-carbon (HLC) behaviours may overlap among certain population groups and/or within

23 specific environments. Nevertheless, it remains unclear whether these behaviours actually co-occur

24 within the same individuals, as there are very few studies that have examined HLC travel and dietary

25 behaviours in relation to each other. For example, evidence from surveys and psychological research

26 has shown that people who are willing to drive less (or drive more efficiently) are also more willing to

1 reduce their meat consumption, but these associations have been limited to behavioural intentions

2 rather than actual travel behaviour and food consumption [23-25]. At the same time, there is

3 considerable evidence of positive associations between physical activity and consuming more

4 healthful diets [26-29], but it is not known whether this relationship also extends to forms of physically

5 active *travel* or to diets that are both healthy and low-carbon. Based on this evidence, it has been

6 proposed that strategies to promote active travel could also offer additional population health benefits

7 through indirect dietary outcomes [30], but these relationships are poorly understood and have not yet

8 been tested empirically. Determining whether behaviours co-occur is important because if behaviours

9 are related, engaging in one behaviour may modify the likelihood of engaging in another [31-34]. This

10 means that strategies which target multiple behaviours together may have additional benefits over the

11 sum of individual interventions [35], and therefore have the potential to produce synergistic outcomes.

12

13 In light of these gaps, the objective of this study was to explore relationships between HLC behaviours

14 in the travel and dietary domains, by examining associations between engaging in active travel and

15 consumption of two food groups (FV, RPM) that have contrasting implications for human health and

16 carbon emissions. Our choice of measures was based on the behaviours for which there are UK

17 government recommendations and for which there is the greatest evidence of combined public health

18 and environment benefits. As far as we are aware, there has been no prior research that has explicitly

19 examined the relationships between these combinations of diet and travel behaviour.

20 **METHODS**

21 **Study design and sample**

22 We used baseline data from UK Biobank (project 14840) to assess cross-sectional relationships

23 between use of different travel modes and dietary consumption. The scientific rationale, study design,

24 and survey methods for UK Biobank (UKB) have been described elsewhere [36]. Briefly, data were

25 collected from 502,616 individuals aged 40–69 years recruited between 2006 and 2010. Participants

1   were identified from National Health Service patient registers and invited to attend one of 22

2   assessment centres located throughout the UK. At each assessment centre, participants

3   completed a touchscreen questionnaire that collected information on socio-demographic

4   characteristics and diet, lifestyle, and environmental factors. UKB received ethics approval from the

5   National Information Governance Board for Health and Social Care and the National Health Service

6   North West Centre for Research Ethics Committee (Ref: 11/NW/0382).

7   In this study, participants who did not provide any information on travel mode use (n=7,272) or dietary

8   consumption (FV or RPM, n=1,820) were excluded, yielding an initial sample size of 493,524. This

9   number was then further restricted to participants who had complete data on all analytical covariates

10   (n=412,299 for all journeys, n=234,148 for commuting journeys). Sensitivity analyses were conducted

11   with a further subsample that had complete data on weekly physical activity (PA) and total energy

12   intake (95,475 females and 83,213 males).

13   **Measures**

14   Travel mode use

15   Data on travel behaviour were collected on the touchscreen questionnaire. Participants were asked to

16   report which travel mode(s) they used for non-work journeys (*In the last 4 weeks, which forms of*

17   *transport have you used most often to get about?*) and for their travel to work (commuting journeys), if

18   they were currently employed and did not always work from home (*What types of transport do you*

19   *use to get to and from work?*). Both questions had the same response options (car/motor vehicle,

20   public transport, walking, cycling), and allowed participants to select multiple modes for each type of

21   journey.

22   Using these two questions, we categorised travel behaviour in several ways. First, to create an overall

23   measure of active travel for each participant, we combined the responses from the two travel

24   questions into one binary variable which included those who reported any walking or any cycling for

1. either non-work or commuting journeys. Similar binary variables were also created for any walking

2. and any cycling across the two types of journeys. Second, to account for all possible combinations of

3. travel, a 15-category travel mode variable was derived for each type of journey (non-work,

4. commuting) in order to organize the modal combinations from those producing the most carbon

5. emissions and requiring the least physical exertion (car use only), to those producing the least

6. emissions and requiring the most physical exertion (cycling only or cycling + walking). This was then

7. collapsed into an eight-category variable for each type of journey: (1) car only, (2) car + public

8. transport only, (3) car + public and active transport, (4) car + active transport only, (5) public transport

9. only, (6) public + active transport, (7) walking only, (8) cycling only or cycling + walking. This approach

10. is similar to that used previously by Flint and Cummins [37].

11.

12. Dietary consumption

13. Data on FV and RPM consumption also came from the touchscreen questionnaire. Participants were

14. asked to report their FV consumption via four open-ended questions that asked about the average

15. number of tablespoons of vegetables and pieces of fruit consumed each day. These responses were

16. then recoded into standard '5-a-day' portions [38] that resulted in an overall measure of average

17. portions of FV consumed for each participant. To assess whether each participant's consumption was

18. in line with the recommended guideline, this variable was also recoded into a three-level ordinal

19. measure: <3, 3 to <5, and 5+ portions/day.

20. Participants were asked five questions about their average weekly intake of different types of meat.

21. To create an overall measure of RPM consumption, we combined the four questions involving RPM

22. (beef, lamb, pork, processed meat) into a composite index, based on the number of times each type

23. of meat was consumed on a weekly basis [39]. For each meat type, the responses were coded as

24. follows: Never = 0, Less than once a week = 0.5, Once a week = 1, 2-4 times a week = 3, 5-6 times a

25. week = 5.5, once or more daily = 7. This index variable ranged from 0 to 28, where 0 indicated that

7

1 participants never consumed any RPM and 28 indicated that participants consumed all four types of

2 RPM on a daily basis. Based on the distribution of the resulting index variable, RPM consumption was

3 then grouped into three categories: (1) non-consumers, and consumers spilt at the median frequency:

4 (2) up to 3 times per week, (3) >3 times per week. This approach was used by Bradbury, et al. [39],

5 who showed that those who consume RPM most frequently (>3 times per week) in the UKB sample

6 also consume the largest quantities per day.

7 Covariates

8 Various demographic, socioeconomic, and environmental factors were hypothesised as possible

9 confounders to relationships between travel behaviour and dietary consumption. Demographic

10 covariates were age at baseline, sex, ethnic origin, and household size. Socioeconomic covariates

11 were gross annual household income, number of cars per household, highest educational

12 qualification, and occupational class. We used the National Statistics Socioeconomic Classification for

13 occupation class by converting codes from Standard Occupational Classification (SOC) 2000.

14 Environmental covariates were residential area classification, Townsend deprivation score, and region

15 of UK. Weekly PA (meeting or not meeting PA guideline) and total energy intake (kcal) were used in

16 sensitivity analyses. Those who reported 150 minutes of moderate PA or 75 minutes of vigorous PA

17 per week were considered to meet the current PA guideline [40]. Data on total energy intake came

18 from a 24-h dietary recall questionnaire which was completed at the assessment centre by the last

19 70,000 participants and up to four times by email in the rest of the cohort [41]. For respondents who

20 completed multiple dietary recall questionnaires, we used the average value.

21 Covariates were mostly self-reported on the touchscreen questionnaire, with the exception of

22 occupational class (verbal interview), residential area classification (census), Townsend deprivation

23 score (census), region of UK (assessment centre location), and average energy intake (24-h dietary

24 assessment).

1 **Statistical Analysis**

2 Associations between each measure of travel behaviour and each dietary outcome were examined

3 using multivariate ordinal regression models in Stata/SE 14.0 [42]. We used ordinal logistic regression

4 in order to model the trends in dietary consumption while keeping the 'extremes' as useful categories

5 (e.g. non-consumers of RPM, and those who met or exceeded consumption guidelines). This enabled

6 meaningful interpretation of the relationships with a view to national dietary recommendations and

7 potentially discontinuous changes in the associations between travel and dietary behaviour. Though

8 these relationships could plausibly go in either direction, we modelled them in this way based on

9 previous hypotheses [30] as well as neurocognitive research which suggests that physical activity

10 may be more likely to lead to dietary changes than vice versa [43 44].

11 In Model 1 we examined the bivariate association between each travel variable and each dietary

12 outcome and in Model 2 we adjusted for socio-demographic and environmental covariates. As a

13 sensitivity analysis we further adjusted for physical activity and energy intake (Model 3) in the

14 subsample with complete data on these factors (for comparison purposes Models 1 and 2 were re-run

15 in this subsample as well). This sensitivity analysis was only conducted for the any active travel

16 variable since this contained all of the other active travel combinations.

17 In each regression model, we tested the proportional odds assumption using the Stata *oparallel* post-

18 estimation command [45]. Where this assumption was not met (p<0.05), we re-ran each model as a

19 generalised ordered logit model (Stata extension *gologit2*) which relaxes the proportional odds

20 assumption for some predictor variables while maintaining it for others [46]. This approach has the

21 advantages of being more parsimonious and interpretable than those estimated by a non-ordinal

22 method and may also give added insights (e.g. discontinuous changes) into the data that would be

23 lost by ignoring the differences and continuing to use the fully ordinal model [47]. We present odds

24 ratios (OR) or adjusted odds ratios (aOR) with 95% confidence intervals (CI) and set a threshold of

1   alpha=0.05 for statistical significance. All analyses were stratified by sex due to established gender

2   differences in the patterning of travel behaviour and dietary consumption in the UK population [19 21

3   48 49].

4   **Patient and Public Involvement**

5   This study was conducted using the UK Biobank resource. Details of patient and public involvement in

6   the UK Biobank are available online (https://www.ukbiobank.ac.uk/public-consultation/). No patients

7   were specifically involved in setting the research question or the outcome measures, nor were they

8   involved in developing plans for recruitment, design or implementation of this study. No patients were

9   asked to advise on interpretation or writing up of results. There are no specific plans to disseminate

10   the results of the research to study participants, but the UK Biobank disseminates key findings from

11   projects on its website (https://www.ukbiobank.ac.uk/participant-events/).

12   **RESULTS**

13   Descriptive characteristics of the sample are presented in Table 1. As well as being older, UK Biobank

14   participants are more socioeconomically advantaged, and more health-conscious in comparison with

15   the UK general population [50]. In this study 54.5% of the sample reported walking or cycling for either

16   type of journey (any active travel), and walking was much more common than cycling (51.6% vs.

17   9.4%) (Table 2). Car only travel was much higher for commuting journeys (63.1%) than for non-work

18   journeys (39.5%), indicating that people were more likely to use multiple modes and more active

19   modes for non-work travel. For example, 22.0% of the sample mixed car use with active modes, and

20   14.0% mixed car, active modes and public transport use for non-work journeys. For diet, 58.3% of

21   males and 36.7% of females reported consuming RPM more than three times per week and only

22   5.3% of the sample reported never consuming any RPM (3.4% among males, 7.0% among females)

23   (Table 3). Nearly 39% reported consuming 5+ portions of FV per day on average (31.4% among

24   males, 43.3% among females).

1   Associations between travel modes and FV consumption

2   Across all models, there were positive associations between all types of HLC travel and FV
3   consumption among both males and females, with very little change even after adjustment for
4   demographic, socioeconomic, and environmental factors (Table 4). Associations were generally much
5   stronger for cycling than for other travel modes. For example, in the fully adjusted models (Model 2),
6   men and women who engaged in any cycling travel were nearly twice as likely to consume higher
7   amounts of FV than those who did not cycle for transport (males: aOR=1.65, 95%CI 1.61, 1.69;
8   females: aOR=1.67, 95%CI 1.62, 1.73). Across the more detailed travel classifications of non-work
9   and commuting journeys, associations were generally weaker or non-significant for travel that did not
10   involve any walking or cycling (e.g. car + public transport, public transport only). Comparing across
11   the two types of journeys, the associations were fairly similar in magnitude, though they were slightly
12   stronger for non-work travel, and particularly for non-work cycling. Based on the confidence intervals,
13   women who engaged in any active travel (aOR=1.43, 95%CI 1.40, 1.45) or any walking travel
14   (aOR=1.38, 95%CI 1.36, 1.41) were more likely to consume higher amounts of FV compared with
15   males (aOR=1.35, 95%CI 1.33, 1.37 and aOR=1.25, 95%CI 1.23, 1.27, respectively). For non-work
16   journeys, the same was also true for women who used car + active travel, walking only, and cycling /
17   cycling + walking, compared with their male counterparts.

18   Associations between travel modes and RPM consumption

19   Overall, the associations between HLC travel and RPM consumption were nearly all negative; the
20   only exception was for car + public transport (versus car only travel) among females for non-work
21   journeys (Table 5). Among both males and females, associations were only slightly attenuated with
22   adjustment for demographic, socioeconomic, and environmental factors. As with FV consumption,
23   these associations were strongest for cycling, overall and across both types of journeys. Moreover,
24   there was a clear gradient of effect for non-work travel, such that the more active the travel mode(s),

11

1　the more negative the association with RPM consumption frequency. For example, in the fully

2　adjusted models (Model 2), men and women who cycled for non-work journeys were nearly half as

3　likely to consume RPM more frequently than those who travelled by car (males: aOR=0.57; 95%CI

4　0.54, 0.60; females: aOR=0.54, 95%CI 0.50, 0.59).

5　Proportional odds assumption

6　Due to the very large sample size in UKB, we were able to detect very minor variations in the data,

7　and this meant that all of the models in Tables 4 and 5 had violations of the proportional odds

8　assumption. To assess whether these differences were meaningful for the key variables of interest

9　(travel variables), all of the models were re-run using a generalised ordered logit model

10　(Supplementary Appendix). Here the associations were generally of similar magnitude and in the

11　same direction to the fully ordinal models, but where differences were present, the associations

12　tended to be slightly stronger for the two highest categories versus the lowest category of the

13　outcome variables, for example, 3+ portions of FV versus <3, and RPM consumers versus never

14　consumers. This relatively trivial difference does not alter the directions of the associations (positive

15　and negative) in our main findings.

16

17　Sensitivity analyses

18　In the subset of the sample with full data on energy intake and physical activity (n=95,475 females,

19　n=83,213 males), adjusting for these variables in addition to the other socio-demographic and

20　environmental factors slightly attenuated the associations between any active travel and FV

21　consumption, but the relationship was still independent and highly significant among both males and

22　females (males: aOR=1.28; 95%CI 1.24, 1.31 and females: aOR=1.35, 95%CI 1.32, 1.39)

23　(Supplementary Appendix). Similarly, the associations between any active travel and RPM

24　consumption were also very slightly attenuated, but even less so than for FV consumption (males:

25　aOR= 0.89; 95%CI 0.87, 0.92 and females: aOR=0.90, 95%CI 0.88, 0.92) (Supplementary Appendix).

12

1 **DISCUSSION**

2 To our knowledge, this is the first analysis to explicitly examine relationships between engaging in

3 active travel and HLC dietary consumption, thus beginning to clarify the patterning of HLC lifestyles.

4 We have shown that engaging in active travel, and in particular cycling, is associated with increased

5 consumption of FV and with reduced consumption of RPM in the UKB sample. In almost all cases, the

6 associations were robust to adjustment by both socio-demographic and behavioural factors,

7 suggesting that these factors do not explain the observed relationships. Using multiple measures of

8 travel and dietary behaviour, we have assessed these relationships comprehensively across different

9 travel modes, types of journeys, and relevant food groups, and also adjusted for a wide range of

10 important covariates. This level of detail has allowed us to isolate and elucidate where the

11 relationships between these HLC behaviours are strongest and weakest, which is an important

12 contribution to understanding which elements of travel and dietary behaviour may share common

13 underlying factors.

14 The major strength of this study is the large sample size and flexible measures of travel behaviour in

15 the UKB dataset, both of which enabled the observation of relatively fine-grained differences in the

16 data. Nevertheless, UKB is limited by its lack of representativeness, as it is based on a sample of

17 'healthy volunteers' [50] and excludes large segments of the population (e.g. those under age 40).

18 The data were also collected between 2006 and 2010, and there have been some population changes

19 in meat consumption since then, though less so among those in the UKB age range [51]. As a result,

20 it is unclear whether these results are generalizable to the UK general population, however similar

21 relationships were also found when this analysis was replicated in a nationally representative UK

22 sample [52 53], which supports the external validity of these associations.

23 Other limitations include that the measures used were all self-reported and that the analyses are

24 cross-sectional. If participants were more likely to report that they walked, cycled, ate more FV and

25 ate less RPM, then this might partially explain the observed associations between these behaviours.

13

1 The cross-sectional nature of the data means we cannot establish causality between these

2 behaviours in terms of whether active travel precedes higher FV and lower RPM consumption, vice

3 versa, or whether change occurs in tandem, or when in the life course such patterns emerge or

4 change. Future research with longitudinal data will help to confirm the direction of these relationships,

5 as well as improve our understanding of behaviour dynamics over time.

6 Importantly, the findings of this study confirm much of the wider evidence on links between health and

7 environmental behaviours, and represent some of the strongest evidence to date on this topic.

8 Several studies have reported clustering between increased physical activity and more nutritious diets

9 [26-29 54], but this study is the first to show that comparable associations exist for *physically active*

10 *travel* and healthy diets, independent of overall physical activity. Our findings also build upon studies

11 of environmental behaviours which have linked reduced car driving with reduced meat consumption,

12 but which have only measured behavioural intentions [24 25]. More indirectly, there are also

13 interesting parallels between this study and the growing body of evidence relating active travel, and

14 particularly active commuting, to positive health outcomes like lower obesity and reduced mortality [19

15 37 55-58]. Two of these studies, also conducted using UKB but only examining active commuting,

16 have found particularly strong effects for cycling to work and lower obesity [37] and reduced mortality

17 [57], far over and above the effects found for walking. Combining these findings with our results on the

18 dietary patterns of cyclists suggests that positive interactions between cycling travel and HLC diets

19 could be one factor contributing to the enhanced health effects observed among individuals who

20 cycle.

21 This study has several important implications. Firstly, the results suggest that active travel and HLC

22 diets may be related and share similar determinants within individuals. Theoretical understandings of

23 behavioural co-occurrence suggest that behaviours which cluster together share common causal

24 pathways [31 32], and that the stronger the relationship between two behaviours, the more

25 determinants they are likely to share [59]. In this study, strong relationships were seen most clearly

14

1   between cycling and FV consumption, even after adjusting for socio-demographic characteristics and

2   behavioural factors like overall physical activity and energy intake. This suggests that these

3   behaviours may be driven by common underlying factors, and supports the interpretation of both

4   behaviours being related to health motivations, though there may also be other factors at play.

5   Identifying whether two behaviours are related is important because strongly associated behaviours

6   may influence each other in different ways [31-34]. In the case of positive relationships, this could

7   mean that related behaviours have the potential to produce synergistic outcomes, if strategies that

8   target multiple HLC behaviours together have greater benefits than the sum of individual interventions

9   [35]. Urgent changes in lifestyles are needed if we are to avoid catastrophic climate change [60 61].

10   Putting these changes into action requires that we have a complete understanding of people's

11   behaviour patterns, including how different behaviours influence, interact and intersect with one

12   another across the life course. Though relationships between active travel and diet still need to be

13   examined longitudinally, this study suggests that these HLC behaviours may have the potential to

14   positively influence one another, and that promotion of these behaviours could help foster enhanced

15   benefits for both human health and the natural environment.

16   **Contributors**

17   All authors made substantial contributions to the conception and design of the study and interpretation

18   of data. MAS undertook the statistical analysis with input from JRB and SLP. MAS drafted the article

19   and all authors revised it critically for important intellectual content. All authors approved the final

20   version of the manuscript to be published.

8 Additional data available in Supplemental Appendix. Dataset can be obtained from UK Biobank.

9

10 **Licence statement**

11 I, the Submitting Author has the right to grant and does grant on behalf of all authors of the Work (as

12 defined in the below author licence), an exclusive licence and/or a non-exclusive licence for

13 contributions from authors who are: i) UK Crown employees; ii) where BMJ has agreed a CC-BY

14 licence shall apply, and/or iii) in accordance with the terms applicable for US Federal Government

15 officers or employees acting as part of their official duties; on a worldwide, perpetual, irrevocable,

16 royalty-free basis to BMJ Publishing Group Ltd ("BMJ") its licensees and where the relevant Journal is

17 co-owned by BMJ to the co-owners of the Journal, to publish the Work in BMJ Open and any other

18 BMJ products and to exploit all rights, as set out in our licence.

19 The Submitting Author accepts and understands that any supply made under these terms is made by

20 BMJ to the Submitting Author unless you are acting as an employee on behalf of your employer or a

21 postgraduate student of an affiliated institution which is paying any applicable article publishing

22 charge ("APC") for Open Access articles. Where the Submitting Author wishes to make the Work

23 available on an Open Access basis (and intends to pay the relevant APC), the terms of reuse of such

24 Open Access shall be governed by a Creative Commons licence – details of these licences and

25 which Creative Commons licence will apply to this Work are set out in our licence referred to above.

Urban residence		167,547	85.9	186,617	85.9	354,164	85.9
Townsend score (mean, sd) [e]		-1.37	3.1	-1.37	3.0	-1.37	3.0

[a] Continuous variable in models

[b] A levels: academic advanced-levels, post compulsory education; GCSEs: academic General Certificate of Secondary Education, formerly Ordinary Levels, taken at age 15–16 years and the end of compulsory education ; CSEs: vocational Certificate of Secondary Education, formerly taken at age 15–16 years; NVQ, HND, HNC: National Vocational Qualifications, Higher National Diploma, Higher National Certificate, all intermediate semi-vocational qualifications

[c] Based on National Statistics Socio-economic Classification (NS-SEC), where Not classified = those who were retired, unemployed, looking after home/family, unable to work because of sickness/disability, doing unpaid/voluntary work, or full-time students

[d] Grouped based on assessment centre: London = St Barts, Croydon, Hounslow; South East England = Oxford, Reading; South West England = Bristol; East Midlands = Nottingham; West Midlands = Birmingham; Yorkshire and the Humber = Leeds, Sheffield; North East England = Middlesbrough, Newcastle; North West England = Liverpool, Manchester, Bury; Wales = Cardiff, Swansea, Wrexham; Scotland = Glasgow, Edinburgh.

[e] Lower score = less deprived (min: -6.3; max: 11.0)

Table 2 – Descriptive overview of travel mode use (n=412,299)

STROBE 2007 (v4) checklist of items to be included in reports of observational studies in epidemiology*

Checklist for cohort, case-control, and cross-sectional studies (combined)

Section/Topic	Item #	Recommendation	Reported on page #
Title and abstract	1	(*a*) Indicate the study's design with a commonly used term in the title or the abstract	1, 2
		(*b*) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4, 5
Objectives	3	State specific objectives, including any pre-specified hypotheses	5
Methods			
Study design	4	Present key elements of study design early in the paper	5, 6
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	5, 6
Participants	6	(*a*) *Cohort study*—Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up *Case-control study*—Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls *Cross-sectional study*—Give the eligibility criteria, and the sources and methods of selection of participants	5, 6
		(*b*) *Cohort study*—For matched studies, give matching criteria and number of exposed and unexposed *Case-control study*—For matched studies, give matching criteria and the number of controls per case	
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	6, 7, 8
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	6, 7, 8
Bias	9	Describe any efforts to address potential sources of bias	9
Study size	10	Explain how the study size was arrived at	6
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	6, 7, 8
Statistical methods	12	(*a*) Describe all statistical methods, including those used to control for confounding	9
		(*b*) Describe any methods used to examine subgroups and interactions	9, 10
		(*c*) Explain how missing data were addressed	6
		(*d*) *Cohort study*—If applicable, explain how loss to follow-up was addressed *Case-control study*—If applicable, explain how matching of cases and controls was addressed	

		Cross-sectional study—If applicable, describe analytical methods taking account of sampling strategy	
		(*e*) Describe any sensitivity analyses	8
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	6
		(b) Give reasons for non-participation at each stage	NA
		(c) Consider use of a flow diagram	
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	10, 17, 18, 19, 20
		(b) Indicate number of participants with missing data for each variable of interest	6, 19, 20
		(c) *Cohort study*—Summarise follow-up time (eg, average and total amount)	
Outcome data	15*	*Cohort study*—Report numbers of outcome events or summary measures over time	
		Case-control study—Report numbers in each exposure category, or summary measures of exposure	
		Cross-sectional study—Report numbers of outcome events or summary measures	10
Main results	16	(*a*) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	11, 12, 21, 22
		(*b*) Report category boundaries when continuous variables were categorized	7, 8, 20
		(*c*) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	9
Discussion			
Key results	18	Summarise key results with reference to study objectives	13
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	13, 14
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	14, 15
Generalisability	21	Discuss the generalisability (external validity) of the study results	13
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	15

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. 1 **ABSTRACT**

2

3 **Objectives** To examine whether there are associations between active travel and markers of a

4 healthy, low-carbon diet (increased consumption of fruit and vegetables, reduced consumption of red

5 and processed meat).

6

7 **Design** Cross-sectional analysis of a cohort study.

8

9 **Settings** Population cohort of over 500,000 people recruited from 22 centres across the United

10 Kingdom. Participants aged between 40 and 69 years were recruited between 2006 and 2010.

11

12 **Participants** 412,299 adults with complete data on travel mode use, consumption of fruit and

13 vegetables and red and processed meat, and socio-demographic covariates were included in the

14 analysis.

15

16 **Exposure measures** Mutually exclusive mode or mode combinations of travel (car, public transport,

17 walking, cycling) for non-work and commuting journeys.

18

19 **Outcome measures** Consumption of fruit and vegetables (FV) measured as portions per day and red

20 and processed meat (RPM) measured as frequency per week.

21

22 **Results** Engaging in all types of active travel was positively associated with higher FV consumption

23 and negatively associated with more frequent RPM consumption. Cycling exclusively or in

24 combination with walking was most strongly associated with increased dietary consumption of FV and

25 reduced consumption of RPM for both non-work and commuting journeys. Overall, the strongest

26 associations were between non-work cycling and FV consumption (males: adjusted odds ratio=2.18,

27 95% confidence interval=2.06, 2.30; females: 2.50, 2.31, 2.71) and non-work cycling and RPM

28 consumption (males: 0.57, 0.54, 0.60; females: 0.54, 0.50, 0.59). Associations were generally similar

29 for both commuting and non-work travel, and were robust to adjustment with socio-demographic and

30 behavioural factors.

31

32 **Conclusions** There are strong associations between engaging in active travel, particularly cycling,

33 and healthy, low-carbon (HLC) dietary consumption, suggesting that these HLC behaviours are

34 related. Further research is needed to better understand the drivers and dynamics between these

35 behaviours within individuals, and whether they share common underlying causes.

5   3   **Article summary**
6
7   4   **Strengths and limitations of this study**
8
9
10   5   • This study uses the UK Biobank to examine associations between active travel and diet in
11   6   order to better understand the patterning of healthy, low-carbon lifestyles.
12
13   7   • UK Biobank is a large cohort with very rich data, which enabled assessment of relationships
14
15   8   using several measures of travel and dietary behaviour and adjustment for a wide range of
16   9   socio-demographic, environmental, and behavioural covariates.
17
18   10   • The analysis used in this study is cross-sectional and therefore we cannot infer causality
19   11   between these behaviours.
20
21   12   • This study is further limited by the use of self-reported measures of active travel and dietary
22
23   13   consumption.

1 **INTRODUCTION**

2 Increasing concerns about global climate change combined with rising rates of chronic disease have

3 led to greater policy attention on behaviours and lifestyles that are beneficial for both human health and

4 the natural environment [1-3]. From this perspective, two priority behaviours that have been identified

5 are engaging in healthy, low-carbon travel (e.g. walking and cycling for transport) and consuming

6 healthy, low-carbon diets (e.g. reduced consumption of meat, increased consumption of fruit and

7 vegetables) [4-8]. Modelling studies have shown that a population shift toward these behaviours would

8 lead to a range of health and environmental co-benefits: increased life expectancies, decreased rates

9 of Type 2 diabetes, cardiovascular diseases and cancer, as well as large reductions in transport and

10 food-related greenhouse gas emissions [3 6 7 9-12]. These shifts are also in line with national health

11 guidelines. In the UK, for example, walking and cycling for transport is widely recommended as a key

12 strategy to increase population physical activity [13 14], and adults are advised to base two-thirds of

13 their diet on plant-sourced foods, specifically consuming at least 5 portions of fruit and vegetables (FV)

14 and less than 70 grams (g) of red and processed meat (RPM) per day to prevent chronic disease

15 outcomes [15 16]. These dietary principles are also in alignment with the recently published 'planetary

16 health diet' which argues that huge changes in consumption of fruits, vegetables, and red meat are

17 needed on a global scale if we are to stay within safe planetary boundaries [17].

18

19 In the UK, studies that have examined these travel and dietary behaviours at the population level have

20 found that they are strongly patterned by socio-demographic factors [18-22], which suggests that

21 healthy, low-carbon (HLC) behaviours may overlap among certain population groups and/or within

22 specific environments. Nevertheless, it remains unclear whether these behaviours actually co-occur

23 within the same individuals, as there are very few studies that have examined HLC travel and dietary

24 behaviours in relation to each other. For example, evidence from surveys and psychological research

25 has shown that people who are willing to drive less (or drive more efficiently) are also more willing to

26 reduce their meat consumption, but these associations have been limited to behavioural intentions

1   rather than actual travel behaviour and food consumption [23-25]. At the same time, there is

2   considerable evidence of positive associations between physical activity and consuming more healthful

3   diets [26-29], but it is not known whether this relationship also extends to forms of physically active

4   *travel* or to diets that are both healthy and low-carbon. Based on this evidence, it has been proposed

5   that strategies to promote active travel could also offer additional population health benefits through

6   indirect dietary outcomes [30], but these relationships are poorly understood and have not yet been

7   tested empirically. Determining whether behaviours co-occur is important because if behaviours are

8   related, engaging in one behaviour may modify the likelihood of engaging in another [31-34]. This

9   means that strategies which target multiple behaviours together may have additional benefits over the

10   sum of individual interventions [35], and therefore have the potential to produce synergistic outcomes.

11   Indeed, this potential for positive interactions makes it particularly important to tease out relationships

12   between active travel and dietary consumption, as it is possible that the observed associations between

13   walking/cycling and better health outcomes in the literature may be partially attributable to the dietary

14   patterns of active travellers (and/or vice versa).

15   In light of these gaps, the objective of this study was to explore relationships between HLC behaviours

16   in the travel and dietary domains, by examining associations between engaging in active travel and

17   consumption of two food groups (FV, RPM) that have contrasting implications for human health and

18   carbon emissions. Our choice of measures was based on the behaviours for which there are UK

19   government recommendations and for which there is the greatest evidence of combined public health

20   and environment benefits. As far as we are aware, there has been no prior research that has explicitly

21   examined the relationships between these combinations of diet and travel behaviour.

22

1   **METHODS**

2   **Study design and sample**

3   We used baseline data from UK Biobank (project 14840) to assess cross-sectional relationships

4   between use of different travel modes and dietary consumption. The scientific rationale, study design,

5   and survey methods for UK Biobank (UKB) have been described elsewhere [36]. Briefly, data were

6   collected from 502,616 individuals aged 40–69 years recruited between 2006 and 2010. Participants

7   were identified from National Health Service patient registers and invited to attend one of 22

8   assessment centres located throughout the UK. At each assessment centre, participants completed

9   a touchscreen questionnaire that collected information on socio-demographic characteristics and

10   diet, lifestyle, and environmental factors. UKB received ethics approval from the National Information

11   Governance Board for Health and Social Care and the National Health Service North West Centre for

12   Research Ethics Committee (Ref: 11/NW/0382).

13   In this study, participants who did not provide any information on travel mode use (n=7,272) or dietary

14   consumption (FV or RPM, n=1,820) were excluded, yielding an initial sample size of 493,524. This

15   number was then further restricted to participants who had complete data on all analytical covariates

16   (n=412,299 for all journeys, n=234,148 for commuting journeys). Sensitivity analyses were conducted

17   with a further subsample that had complete data on weekly physical activity (PA) and total energy intake

18   (95,475 females and 83,213 males).

19   **Measures**

20   Travel mode use

21   Data on travel behaviour were collected on the touchscreen questionnaire. Participants were asked to

22   report which travel mode(s) they used for non-work journeys (*In the last 4 weeks, which forms of*

23   *transport have you used most often to get about?*) and for their travel to work (commuting journeys), if

24   they were currently employed and did not always work from home (*What types of transport do you use*

6

1 *to get to and from work?*). Both questions had the same response options (car/motor vehicle, public

2 transport, walking, cycling), and allowed participants to select multiple modes for each type of journey.

3 Using these two questions, we categorised travel behaviour in several ways. First, to create an overall

4 measure of active travel for each participant, we combined the responses from the two travel questions

5 into one binary variable which included those who reported any walking or any cycling for either non-

6 work or commuting journeys. Similar binary variables were also created for any walking and any cycling

7 across the two types of journeys. Second, to account for all possible combinations of travel, a 15-

8 category travel mode variable was derived for each type of journey (non-work, commuting) in order to

9 organize the modal combinations from those producing the most carbon emissions and requiring the

10 least physical exertion (car use only), to those producing the least emissions and requiring the most

11 physical exertion (cycling only or cycling + walking). This was then collapsed into an eight-category

12 variable for each type of journey: (1) car only, (2) car + public transport only, (3) car + public and active

13 transport, (4) car + active transport only, (5) public transport only, (6) public + active transport, (7)

14 walking only, (8) cycling only or cycling + walking. This approach is similar to that used previously by

15 Flint and Cummins [37].

16

17 Dietary consumption

18 Data on FV and RPM consumption also came from the touchscreen questionnaire. Participants were

19 asked to report their FV consumption via four open-ended questions that asked about the average

20 number of tablespoons of vegetables and pieces of fruit consumed each day. These responses were

21 then recoded into standard '5-a-day' portions [38] that resulted in an overall measure of average

22 portions of FV consumed for each participant. To assess whether each participant's consumption was

23 in line with the recommended guideline, this variable was also recoded into a three-level ordinal

24 measure: <3, 3 to <5, and 5+ portions/day.

1 Participants were asked five questions about their average weekly intake of different types of meat. To

2 create an overall measure of RPM consumption, we combined the four questions involving RPM (beef,

3 lamb, pork, processed meat) into a composite index, based on the number of times each type of meat

4 was consumed on a weekly basis [39]. For each meat type, the responses were coded as follows: Never

5 = 0, Less than once a week = 0.5, Once a week = 1, 2-4 times a week = 3, 5-6 times a week = 5.5, once

6 or more daily = 7. This index variable ranged from 0 to 28, where 0 indicated that participants never

7 consumed any RPM and 28 indicated that participants consumed all four types of RPM on a daily basis.

8 Based on the distribution of the resulting index variable, RPM consumption was then grouped into three

9 categories: (1) non-consumers, and consumers split at the median frequency: (2) up to 3 times per

10 week, (3) >3 times per week. This approach was used by Bradbury, et al. [39], who showed that those

11 who consume RPM most frequently (>3 times per week) in the UKB sample also consume the largest

12 quantities per day.

13 Covariates

14 Various demographic, socioeconomic, and environmental factors were hypothesised as possible

15 confounders to relationships between travel behaviour and dietary consumption. Demographic

16 covariates were age at baseline, sex, ethnic origin, and household size. Socioeconomic covariates were

17 gross annual household income, number of cars per household, highest educational qualification, and

18 occupational class. We used the National Statistics Socioeconomic Classification for occupation class

19 by converting codes from Standard Occupational Classification (SOC) 2000. Environmental covariates

20 were residential area classification, Townsend deprivation score, and region of UK.

21 Weekly PA (meeting or not meeting PA guideline) and total energy intake (kcal) were used in sensitivity

22 analyses, due to the complex interrelationships between active travel, physical activity, dietary

23 consumption and energy intake (further details and diagram of putative relationships in Supplementary

24 Appendix, Figure S1). Those who reported 150 minutes of moderate PA or 75 minutes of vigorous PA

25 per week were considered to meet the current PA guideline [40]. Data on total energy intake came from

8

1 a 24-h dietary recall questionnaire which was completed at the assessment centre by the last 70,000

2 participants and up to four times by email in the rest of the cohort [41]. For respondents who completed

3 multiple dietary recall questionnaires, we used the average value.

4 Covariates were mostly self-reported on the touchscreen questionnaire, with the exception of

5 occupational class (verbal interview), residential area classification (census), Townsend deprivation

6 score (census), region of UK (assessment centre location), and average energy intake (24-h dietary

7 assessment).

8 **Statistical Analysis**

9 Associations between each measure of travel behaviour and each dietary outcome were examined

10 using multivariate ordinal regression models in Stata/SE 14.0 [42]. We used ordinal logistic regression

11 in order to model the trends in dietary consumption while keeping the 'extremes' as useful categories

12 (e.g. non-consumers of RPM, and those who met or exceeded consumption guidelines). This enabled

13 meaningful interpretation of the relationships with a view to national dietary recommendations and

14 potentially discontinuous changes in the associations between travel and dietary behaviour. Though

15 these relationships could plausibly go in either direction, we modelled them in this way based on

16 previous hypotheses [30] as well as neurocognitive research which suggests that physical activity may

17 be more likely to lead to dietary changes than vice versa [43 44].

18 In Model 1 we examined the bivariate association between each travel variable and each dietary

19 outcome and in Model 2 we adjusted for socio-demographic and environmental covariates. As a

20 sensitivity analysis we further adjusted for physical activity and energy intake (Model 3) in the

21 subsample with complete data on these factors (for comparison purposes Models 1 and 2 were re-run

22 in this subsample as well). This sensitivity analysis was only conducted for the any active travel variable

23 since this contained all of the other active travel combinations.

24 When interpreting the ordinal logistic model, the model assumes that the relationship between each

9

1 pair of outcome groups is the same, or in other words, that the coefficients describing the relationship

2 between the lowest outcome category and all higher categories are the same as those describing the

3 relationship between the next lowest category and all higher categories, etc. This is called the

4 proportional odds or parallel lines assumption [45], and in this case, the models assume that the odds

5 of being in the lowest dietary consumption category compared to the two highest, are the same as the

6 odds of being in the highest consumption category compared to the two lowest. In each regression

7 model, we tested the proportional odds assumption using the Stata *oparallel* post-estimation command

8 [46]. Where this assumption was not met ($p<0.05$), we re-ran each model as a generalised ordered logit

9 model (Stata extension *gologit2*) which relaxes the proportional odds assumption for some predictor

10 variables while maintaining it for others [47]. This approach has the advantages of being more

11 parsimonious and interpretable than those estimated by a non-ordinal method and may also give added

12 insights (e.g. discontinuous changes) into the data that would be lost by ignoring the differences and

13 continuing to use the fully ordinal model [45]. We present odds ratios (OR) or adjusted odds ratios (aOR)

14 with 95% confidence intervals (CI) and set a threshold of alpha=0.05 for statistical significance. All

15 analyses were stratified by sex due to established gender differences in the patterning of travel

16 behaviour and dietary consumption in the UK population [19 21 48 49].

17 **Patient and Public Involvement**

18 This study was conducted using the UK Biobank resource. Details of patient and public involvement in

19 the UK Biobank are available online (https://www.ukbiobank.ac.uk/public-consultation/). No patients

20 were specifically involved in setting the research question or the outcome measures, nor were they

21 involved in developing plans for recruitment, design or implementation of this study. No patients were

22 asked to advise on interpretation or writing up of results. There are no specific plans to disseminate the

23 results of the research to study participants, but the UK Biobank disseminates key findings from projects

24 on its website (https://www.ukbiobank.ac.uk/participant-events/).

1 **RESULTS**

2 Descriptive characteristics of the sample are presented in Table 1. As well as being older, UK Biobank

3 participants are more socioeconomically advantaged, and more health-conscious in comparison with

4 the UK general population [50]. In this study 54.5% of the sample reported walking or cycling for either

5 type of journey (any active travel), and walking was much more common than cycling (51.6% vs. 9.4%)

6 (Table 2). Car only travel was much higher for commuting journeys (63.1%) than for non-work journeys

7 (39.5%), indicating that people were more likely to use multiple modes and more active modes for non-

8 work travel. For example, 22.0% of the sample mixed car use with active modes, and 14.0% mixed car,

9 active modes and public transport use for non-work journeys. For diet, 58.3% of males and 36.7% of

10 females reported consuming RPM more than three times per week and only 5.3% of the sample

11 reported never consuming any RPM (3.4% among males, 7.0% among females) (Table 3). Nearly 38%

12 reported consuming 5+ portions of FV per day on average (31.4% among males, 43.3% among

13 females).

14 Associations between travel modes and FV consumption

15 Across all models, there were positive associations between all types of HLC travel and FV consumption

16 among both males and females, with very little change even after adjustment for demographic,

17 socioeconomic, and environmental factors (Table 4 and Supplementary Appendix, Figure S2).

18 Associations were generally much stronger for cycling than for other travel modes. For example, in the

19 fully adjusted models (Model 2), men and women who engaged in any cycling travel were nearly twice

20 as likely to consume higher amounts of FV than those who did not cycle for transport (males: aOR=1.65,

21 95%CI 1.61, 1.69; females: aOR=1.67, 95%CI 1.62, 1.73). Across the more detailed travel

22 classifications of non-work and commuting journeys, associations were generally weaker or non-

23 significant for travel that did not involve any walking or cycling (e.g. car + public transport, public

24 transport only). Comparing across the two types of journeys, the associations were fairly similar in

25 magnitude, though they were slightly stronger for non-work travel, and particularly for non-work cycling.

11

1   Based on the confidence intervals, women who engaged in any active travel (aOR=1.43, 95%CI 1.40,

2   1.45) or any walking travel (aOR=1.38, 95%CI 1.36, 1.41) were more likely to consume higher amounts

3   of FV compared with males (aOR=1.35, 95%CI 1.33, 1.37 and aOR=1.25, 95%CI 1.23, 1.27,

4   respectively). For non-work journeys, the same was also true for women who used car + active travel,

5   walking only, and cycling / cycling + walking, compared with their male counterparts. Full models are

6   shown in Supplementary Appendix, Tables S1 and S2.

7   Associations between travel modes and RPM consumption

8   Overall, the associations between HLC travel and RPM consumption were nearly all negative; the only

9   exception was for car + public transport (versus car only travel) among females for non-work journeys

10   (Table 5 and Supplementary Appendix, Figure S3). Among both males and females, associations were

11   only slightly attenuated with adjustment for demographic, socioeconomic, and environmental factors.

12   As with FV consumption, these associations were strongest for cycling, overall and across both types

13   of journeys. Moreover, there was a clear gradient of effect for non-work travel, such that the more active

14   the travel mode(s), the more negative the association with RPM consumption frequency. For example,

15   in the fully adjusted models (Model 2), men and women who cycled for non-work journeys were nearly

16   half as likely to consume RPM more frequently than those who travelled by car (males: aOR=0.57;

17   95%CI 0.54, 0.60; females: aOR=0.54, 95%CI 0.50, 0.59). Full models are shown in Supplementary

18   Appendix, Tables S3 and S4.

19   Proportional odds assumption

20   Due to the very large sample size in UKB, we were able to detect very minor variations in the data, and

21   this meant that all of the models in Tables 4 and 5 had violations of the proportional odds assumption.

22   To assess whether these differences were meaningful for the key variables of interest (travel variables),

23   all of the models were re-run using a generalised ordered logit model (Supplementary Appendix, Tables

24   S5 and S6). Here the associations were generally of similar magnitude and in the same direction to the

12

1   fully ordinal models, but where differences were present, the associations tended to be slightly stronger

2   for the two highest categories versus the lowest category of the outcome variables, for example, 3+

3   portions of FV versus <3, and RPM consumers versus never consumers. This relatively trivial difference

4   does not alter the directions of the associations (positive and negative) in our main findings.

5

6   Sensitivity analyses

7   In the subset of the sample with full data on energy intake and physical activity (n=95,475 females,

8   n=83,213 males), adjusting for these variables in addition to the other socio-demographic and

9   environmental factors slightly attenuated the associations between any active travel and FV

10   consumption, but the relationship was still independent and highly significant among both males and

11   females (males: aOR=1.28; 95%CI 1.24, 1.31 and females: aOR=1.35, 95%CI 1.32, 1.39)

12   (Supplementary Appendix, Tables S7 and S8). Similarly, the associations between any active travel

13   and RPM consumption were also very slightly attenuated, but even less so than for FV consumption

14   (males: aOR= 0.89; 95%CI 0.87, 0.92 and females: aOR=0.90, 95%CI 0.88, 0.92) (Supplementary

15   Appendix, Tables S9 and S10).

16   **DISCUSSION**

17   To our knowledge, this is the first analysis to explicitly examine relationships between engaging in active

18   travel and HLC dietary consumption, thus beginning to clarify the patterning of HLC lifestyles. We have

19   shown that engaging in active travel, and in particular cycling, is associated with increased consumption

20   of FV and with reduced consumption of RPM in the UKB sample. These associations were robust to

21   adjustment by both socio-demographic and behavioural factors, suggesting that these factors do not

22   explain the observed relationships. Using multiple measures of travel and dietary behaviour, we have

23   assessed these relationships comprehensively across different travel modes, types of journeys, and

24   relevant food groups, and also adjusted for a wide range of important covariates. This level of detail has

1 allowed us to isolate and elucidate where the relationships between these HLC behaviours are

2 strongest and weakest, which is an important contribution to understanding which elements of travel

3 and dietary behaviour may share common underlying factors.

4 The major strength of this study is the large sample size and flexible measures of travel behaviour in

5 the UKB dataset, both of which enabled the observation of relatively fine-grained differences in the data.

6 Nevertheless, UKB is limited by its lack of representativeness, as it is based on a sample of 'healthy

7 volunteers' [50] and excludes large segments of the population (e.g. those under age 40). The data

8 were also collected between 2006 and 2010, and there have been some population changes in meat

9 consumption since then, though less so among those in the UKB age range [51]. As a result, it is unclear

10 whether these results are generalizable to the UK general population, however similar relationships

11 were also found when this analysis was replicated in a nationally representative UK sample [52 53],

12 which supports the external validity of these associations.

13 Other limitations include that the measures used were all self-reported and that the analyses are cross-

14 sectional. Due to the health-conscious nature of the cohort, it is possible that consumption of some food

15 groups may be over- or under-reported, however, an in-depth study of the reliability of the UKB

16 touchscreen dietary questionnaire has shown that participant responses for FV and meat consumption

17 are very consistent over time (70-90%) and correlate well with other independent dietary assessments

18 (e.g. 24 hour dietary recall) conducted as part of the larger UKB study [54]. Nonetheless, if participants

19 were more likely to report that they walked, cycled, ate more FV and ate less RPM, then this might

20 partially explain the observed associations between these behaviours. The cross-sectional nature of

21 the data means we cannot establish causality between these behaviours in terms of whether active

22 travel precedes higher FV and lower RPM consumption, vice versa, or whether change occurs in

23 tandem, or when in the life course such patterns emerge or change. Future research with longitudinal

24 data will help to confirm the direction of these relationships, as well as improve our understanding of

25 behaviour dynamics over time.

1 Importantly, the findings of this study confirm much of the wider evidence on links between health and

2 environmental behaviours, and represent some of the strongest evidence to date on this topic. Several

3 studies have reported clustering between increased physical activity and more nutritious diets [26-29

4 55], but this study is the first to show that comparable associations exist for *physically active travel* and

5 healthy diets, independent of overall physical activity. Our findings also build upon studies of

6 environmental behaviours which have linked reduced car driving with reduced meat consumption, but

7 which have only measured behavioural intentions [24 25]. More indirectly, there are also interesting

8 parallels between this study and the growing body of evidence relating active travel, and particularly

9 active commuting, to positive health outcomes like lower obesity and reduced mortality [19 37 56-59].

10 Two of these studies, also conducted using UKB but only examining active commuting, have found

11 particularly strong effects for cycling to work and lower obesity [37] and reduced mortality [58], far over

12 and above the effects found for walking. Combining these findings with our results on the dietary

13 patterns of cyclists suggests that positive interactions between cycling travel and HLC diets could be

14 one factor contributing to the enhanced health effects observed among individuals who cycle.

15 This study has several important implications. Firstly, the results suggest that active travel and HLC

16 diets may be related and share similar determinants within individuals. Theoretical understandings of

17 behavioural co-occurrence suggest that behaviours which cluster together share common causal

18 pathways [31 32], and that the stronger the relationship between two behaviours, the more determinants

19 they are likely to share [60]. In this study, strong relationships were seen most clearly between cycling

20 and FV consumption, even after adjusting for socio-demographic characteristics and behavioural

21 factors like overall physical activity and energy intake. This suggests that these behaviours may be

22 driven by common underlying factors, and supports the interpretation of both behaviours being related

23 to health motivations, though there may also be other factors at play. Since cycling is still a relatively

24 rare form of travel in the UK, these patterns may reflect the fact that people who cycle for transport are

25 somewhat unique, and may also deviate from social norms in other ways (e.g. diet). Future research

26 could explore this area further by examining whether relationships between cycling and dietary

15

1   consumption are consistent in parts of the UK where people cycle at higher frequencies (e.g.

2   Cambridge) [61] or among those who cycle at higher intensities, such as for sport.

3   Identifying whether two behaviours are related is important because strongly associated behaviours

4   may influence each other in different ways [31-34]. In the case of positive relationships, this could mean

5   that related behaviours have the potential to produce synergistic outcomes, if strategies that target

6   multiple HLC behaviours together have greater benefits than the sum of individual interventions [35].

7   Urgent changes in lifestyles are needed if we are to avoid catastrophic climate change [62 63]. Putting

8   these changes into action requires that we have a complete understanding of people's behaviour

9   patterns, including how different behaviours influence, interact and intersect with one another across

10   the life course. Though relationships between active travel and diet still need to be examined

11   longitudinally, this study suggests that these HLC behaviours may have the potential to positively

12   influence one another, and that promotion of these behaviours could help foster enhanced benefits for

13   both human health and the natural environment.

Contributors

MAS, JRB, HG, PCLW and SLP made substantial contributions to the conception and design of the

study and interpretation of data. MAS undertook the statistical analysis with input from JRB and SLP.

MAS drafted the article and JRB, HG, PCLW and SLP revised it critically for important intellectual

content. MAS, JRB, HG, PCLW and SLP approved the final version of the manuscript to be published.

Competing interests

None declared.

Data sharing statement

This study used data from the UK Biobank (www.ukbiobank.ac.uk) which does not permit public

sharing of the data. The data are, however, open to all qualified researchers anywhere in the world

and can be accessed by applying through the UK Biobank Access Management System

(www.ukbiobank.ac.uk/register-apply).

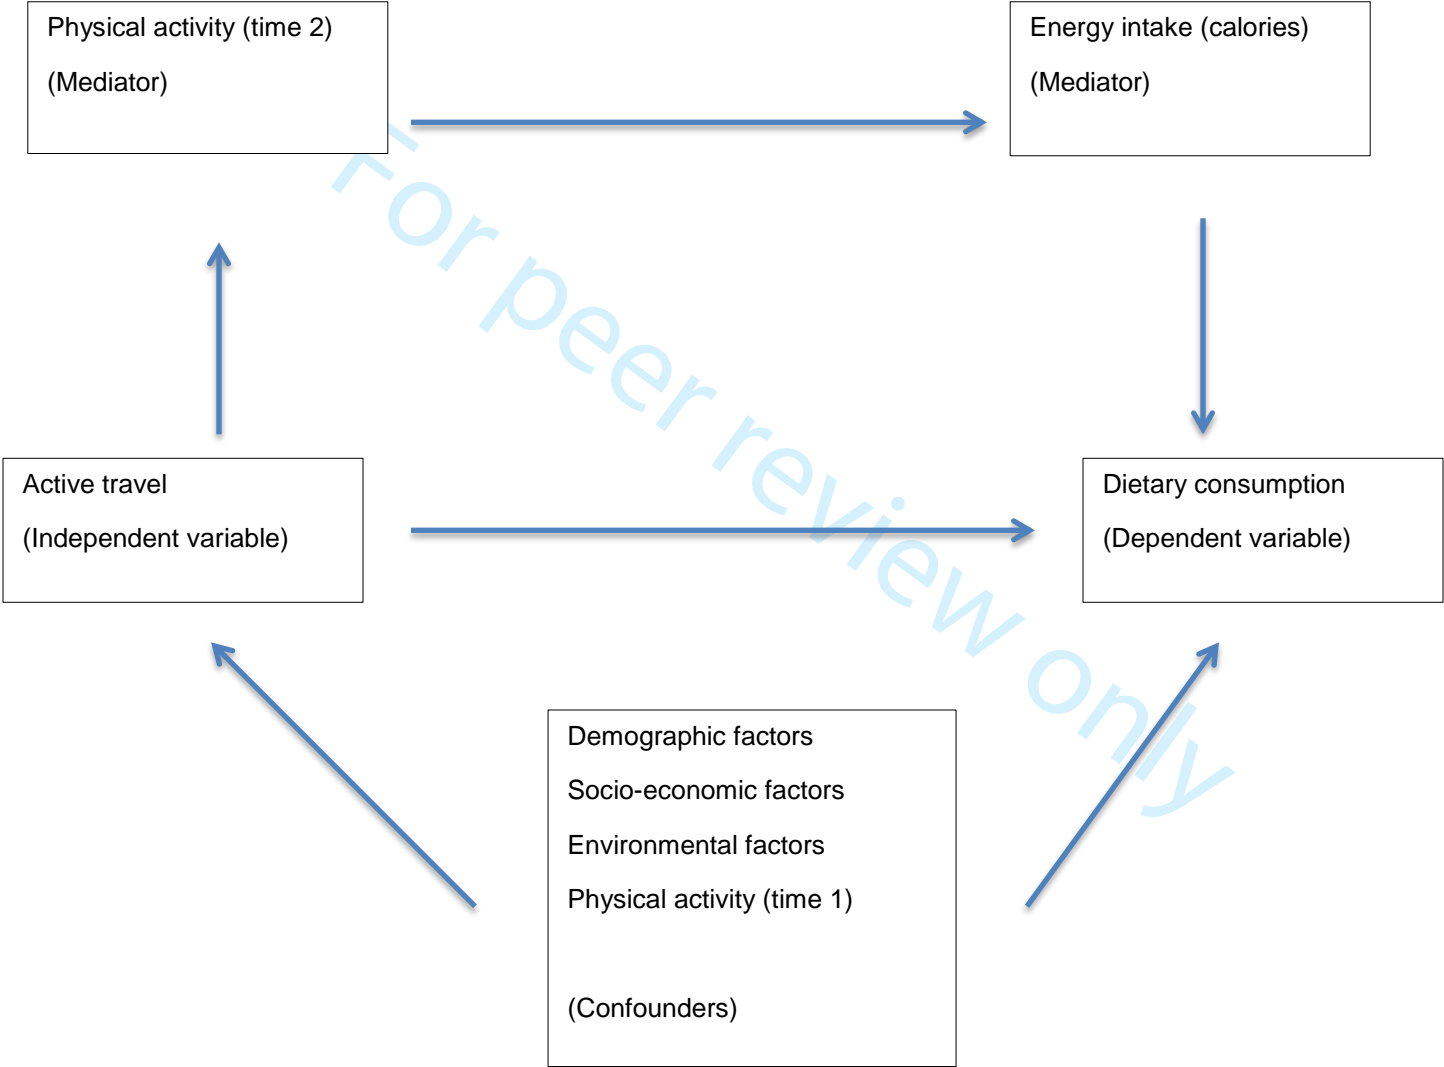

Figure S1 provides an overview of the putative relationships between active travel, dietary consumption, physical activity, energy intake and other covariates in this study.

People who are more physically active tend to have healthier diets [1] and may be more likely to engage in active travel [2] – this means that one's initial physical activity level (time 1) may be a confounder of the relationship between active travel and dietary consumption, in the same way that demographic, socio-economic, and environmental factors may also act as confounders.

At the same time, we also know that those who engage in active travel may accumulate additional physical activity [3], which may ultimately lead them to consume more food and have a higher energy intake (time 2). In this way, it is possible for physical activity and energy intake to act as mediators of the relationship between active travel and dietary consumption.

It is not possible to tease out these distinctions with cross-sectional data, where all of these variables have been measured at the same point in time. To account for this limitation, we have presented three models with different levels of covariate adjustment: Model 1 is unadjusted, Model 2 is adjusted for demographic, socio-economic and environmental factors, and Model 3 (sensitivity analysis) is adjusted for physical activity level and energy intake.

STROBE 2007 (v4) checklist of items to be included in reports of observational studies in epidemiology*

Checklist for cohort, case-control, and cross-sectional studies (combined)

Section/Topic	Item #	Recommendation	Reported on page #
Title and abstract	1	(*a*) Indicate the study's design with a commonly used term in the title or the abstract	1, 2
		(*b*) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4, 5
Objectives	3	State specific objectives, including any pre-specified hypotheses	5
Methods			
Study design	4	Present key elements of study design early in the paper	5, 6
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	5, 6
Participants	6	(*a*) *Cohort study*—Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up *Case-control study*—Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls *Cross-sectional study*—Give the eligibility criteria, and the sources and methods of selection of participants	5, 6
		(*b*) *Cohort study*—For matched studies, give matching criteria and number of exposed and unexposed *Case-control study*—For matched studies, give matching criteria and the number of controls per case	
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	6, 7, 8
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	6, 7, 8
Bias	9	Describe any efforts to address potential sources of bias	9
Study size	10	Explain how the study size was arrived at	6
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	6, 7, 8
Statistical methods	12	(*a*) Describe all statistical methods, including those used to control for confounding	9
		(*b*) Describe any methods used to examine subgroups and interactions	9, 10
		(*c*) Explain how missing data were addressed	6
		(*d*) *Cohort study*—If applicable, explain how loss to follow-up was addressed *Case-control study*—If applicable, explain how matching of cases and controls was addressed	

		Cross-sectional study—If applicable, describe analytical methods taking account of sampling strategy	
		(*e*) Describe any sensitivity analyses	8
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	6
		(b) Give reasons for non-participation at each stage	NA
		(c) Consider use of a flow diagram	
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	10, 17, 18, 19, 20
		(b) Indicate number of participants with missing data for each variable of interest	6, 19, 20
		(c) *Cohort study*—Summarise follow-up time (eg, average and total amount)	
Outcome data	15*	*Cohort study*—Report numbers of outcome events or summary measures over time	
		Case-control study—Report numbers in each exposure category, or summary measures of exposure	
		Cross-sectional study—Report numbers of outcome events or summary measures	10
Main results	16	(*a*) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	11, 12, 21, 22
		(*b*) Report category boundaries when continuous variables were categorized	7, 8, 20
		(*c*) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	9
Discussion			
Key results	18	Summarise key results with reference to study objectives	13
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	13, 14
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	14, 15
Generalisability	21	Discuss the generalisability (external validity) of the study results	13
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	15

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at http://www.plosmedicine.org/, Annals of Internal Medicine at http://www.annals.org/, and Epidemiology at http://www.epidem.com/). Information on the STROBE Initiative is available at www.strobe-statement.org.
