# ABSTRACT

**Objectives** The health-related consequences of electrical shocks are mostly studied in patients from selected cohorts in hospital burn units, by making internal comparisons of subgroups, but without comparing them to unexposed individuals, or considering information regarding the preinjury health of the injured persons. Often, little is known about the details of the electrical shocks. Our purpose was to do a longitudinal study of Danish electrical workers, to monitor exposure to electrical shocks weekly over a 6-month period and to determine whether these shocks have short-term, health-related consequences.

Design Prospective cohort study with weekly measurements.

Setting Members of the Danish Union of Electricians. Participants Of the 22284 invited, 6960 electricians (31%) participated in the baseline data collection, and the participation rate in the weekly follow-up ranged from 61% to 81% during the 6 month follow-up.

Primary and secondary outcome measures The primary outcome measure was an electrical shock and secondary outcomes were the immediate health-related consequences of the shocks.

Results A total of 2356 electrical shocks were reported by 1612 (23%) of the participants during the 26-week follow-up. Alternating current and voltage below 1000 V were the most common forms of electricity. In most cases, the fingers/hands were the entry and exit points, but many were unable to specify the exit point. The participants categorised 73% of the electrical shocks as 'not at all severe', and most of the shocks did not cause any immediate physical damage. However, flashbacks were more common than physical consequences. Only a few of the participants contacted health services following an electrical shock, and even fewer were absent from work. **Conclusion** Nearly one-fourth of Danish electricians experienced one or more electrical shocks during a 26week period, but most of the shocks are not perceived as severe, and have only limited immediate consequences.

# INTRODUCTION

Electrical injuries occur in homes, in public and at all types of workplaces. Despite regulations and safety precautions, both children and adults are injured, although most injuries happen to young men.<sup>1</sup> Electrical workers, such as electricians and technicians working

## STRENGTHS AND LIMITATIONS OF THIS STUDY

- $\Rightarrow$  First prospective cohort study for collecting information on electrical shocks among Danish electricians.
- $\Rightarrow$  The prospective design provides information about health before shocks in future studies.
- $\Rightarrow$  Low participation rate carries the risk of selection bias
- $\Rightarrow$  Possibility of long-term follow-up in health registries.

with electrical installations, are a professional group especially at risk of electrical injuries. When they are injured by electrical shocks, it is rarely a result of ignorance, but more tec often due to miscommunication, working đ without turning off the electrical current or simple sloppiness, perhaps because of time pressure.

Existing knowledge about the frequency Existing knowledge about the frequency of electrical injuries is limited. In Denmark, as in most other countries, non-fatal electrical injuries are not systematically registered, and thus their incidence is unknown. For instance, electrical injuries in Denmark ≥ were registered with The Danish Safety Technology Authority until 2010, but only if the accident was caused by a technical fault in the equipment.<sup>3</sup> Hospitals are another source of information on electrical injuries, where electrical injuries have their own International Classification of Diseases 10th Revision code, which has been increasingly used in Danish hospitals over the last decade. Furthermore, work-related electrical injuries are registered by The Danish Working Environment & Authorities (DWEA). All types of injuries may **g** be registered, but registration is mandatory if the injury results in sick leave for at least the day following the day of the injury.<sup>4</sup> However, it is well-documented that only approximately 50% of occupational injuries are actually reported to DWEA.<sup>5</sup> Thus, under-reporting is likely, and less severe exposure to electrical current is not registered.<sup>6</sup> There is no comprehensive overview of the incidence of

uses rela

text

BMJ

electrical injuries' in Denmark, and this probably applies to other countries as well.

The consequences of exposure to electrical current range from a momentary scare and temporary pain, to severe burns and tissue damage, to death, although fatal electrical injuries are rare in Denmark, with an average of fewer than two per year in a population of 5.8 million.<sup>3</sup> A range of case studies and studies of groups of patients who have suffered an electrical injury suggest a variety of mental and physical symptoms. Some of these are common physical symptoms, such as headaches, muscle pain, sensory disturbances, but mental symptoms, such as cognitive problems, anxiety and depression are also reported.7-9

The purpose of this project was to collect data regarding participants' health previous to their reported electrical shocks, to facilitate unbiased comparisons within and between participants' health and to establish a basis for long-term follow-up in future studies.

The aim of this study was to prospectively monitor and describe electrical shocks and their immediate healthrelated consequences in a cohort of Danish electricians.

#### MATERIALS AND METHODS

This was a 6-month prospective cohort study of Danish electricians, with weekly questionnaires.

#### Setting and data collection

The Danish Union of Electricians has approximately 28000 members, and organises electricians, technicians, apprentices and others electrical workers in Denmark. It is estimated that 67% of all Danish electricians are members. The data collection was conducted from October 2019 to May 2020 and had two parts: a baseline survey and 26 weeks of short, weekly, follow-up questionnaires. The survey content is described later in detail.

Before inviting union members to participate in the cohort, an information campaign about the project was presented to the members through the union's print magazine, webpage, Facebook pages, newsletters, and at member meetings and meetings of work environment representatives. This was done to ensure a high participation rate. To motivate participation, during the enrolment phase and each week of follow-up, we held a lottery for cinema-ticket vouchers for respondents, and three of the eleven local union branches held a lottery for a hotel stay for those who participated in the entire follow-up period.

Invitations to participate in the cohort were emailed to all members of the union who had registered an email address. The information campaign continued in the weeks after the invitations were sent, and along with updates on the project throughout the follow-up period, to motivate the members to respond and to continue responding during the follow-up period. After the initial invitation email, we emailed up to three reminders to the members, approximately 1 week apart. Furthermore,

the union phoned a large number of non-responders, to motivate them to participate.

## **Procedures**

Inclusion in the cohort required agreement to participate in the follow-up period, during which participants received a text message with a link to a short, web-based questionnaire each Wednesday, for 26 consecutive weeks. A small group of participants received the weekly link by email instead of text message, primarily persons working offshore, where phone connections were not stable. The links to the weekly questionnaires remained open to responses throughout the data collection period, but responses were placed according to their actual response date, and shocks reported more than 14 days after the incident were excluded (primarily during the first week of the data collection, some reported shocks from several years before). If a participant did not respond to text message within 24 hours, they received a reminder. If a participant did not respond for two consecutive weeks, the researchers sent an email with a request to respond **B** and continue participating in the study. If the participants did not respond after this, their contact informa-tion was given to their local union branch, where local pants did not respond after this, their contact informarepresentatives tried to phone them and motivate them ſe to continue participating. Not all non-responders were phoned, owning to capacity of personnel in the union ö branches, and some were phoned in vain, or a message was left on their answering service. This telephone reminder procedure was unsystematic, because of variations in the resources of the union branches, and over  $\mathbf{\bar{a}}$ time. ata mining

Data were collected and managed using REDCap electronic data capture tools, hosted by Aarhus University.<sup>10</sup>

## Content of the baseline and weekly follow-up web-based surveys

l training The baseline survey consisted of questions about the participants, their health and their perception of their health. This included questions about symptoms and മ recent exposure to electrical shocks, as in the weekly questionnaire (online supplemental file 1). Questions about recent exposure to electrical shock were designed so the participants were only presented with questions that were relevant to them, based on the answers they gave. Most notably, the participants responded to a range of detailed questions about the characteristics and consequences of **g** a shock only if they reported having experienced an elec-  $\overline{\mathbf{g}}$ trical shock.

The weekly follow-up questionnaires included questions on electrical shock exposure, and posed questions on absenteeism, ability to work and single-item versions of the symptom scales used in the baseline survey (online supplemental file 1), regardless of the participant's exposure to electrical shock, to prospectively monitor the participant's health prior to any electrical injury that might eventually occur.

## **Open** access

#### Patient and public involvement statement

When we designed and planned the project, we involved a steering group of members from the electricians' union and other organisations that addressed electricity and technical safety, to ensure that the participants would be able to understand questionnaires, and that they covered relevant aspects of electrical injuries. We also tested the questionnaire on a small group of electricians before the final version was launched.<sup>11-18</sup>

#### Linkage of data

Every person working and living in Denmark has a unique personal identification number, called the CPR number.<sup>19</sup> The participants consented to the use of their CPR numbers for later follow-up in registries. Each Danish citizen as well as registered migrant workers holds this unique CPR number that provide the possibility to link each person across different registries. This makes it possible to study outcomes after the relatively short follow-up survey. In this study, the CPR number was used to determine participant sex and age.

#### **Analysis**

Data were presented as counts and percentages, including information about missing data. Participants were compared with non-participants with regard to age and sex. Details regarding exposure to electrical shocks and their immediate consequences were described, and participation and proportions of electrical shocks over time were presented graphically. All data management and analysis were conducted in Stata V.16.1

#### RESULTS Participation

We invited 22 284 members of the Danish Union of Electricians to participate, excluding members without an email address, and retired members. Of these, 6960 agreed to ē

le X

I training, and similar technologies

participate, but 50 did not complete the baseline questionnaire. Table 1 provides demographic information for respondents compared with non-respondents, and other baseline characteristics. The proportion of women and of persons over 30 was larger among respondents than non-respondents, in line with other population-based studies. Most of the participants were trained electricians, and apprentices were the second largest group. They reported slightly better health than the Danish population in general, and reported lower alcohol use, whereas the smoking habits and body mass index were in line with the Danish male population.<sup>20</sup>

#### Participation during follow-up

Protected by copyright, The weekly response rate declined from 81% to 62% during the first 11 weeks of follow-up. After that, the response rate stabilised at approximately 63% for the rest of the data collection period (figure 1).

#### **Electrical shocks**

including During the 26 weeks of follow-up, 2356 electrical shocks were reported with 1133 persons (16.3%) reporting 2 r uses one shock, 319 persons (4.6%) reporting two shocks, 97 persons (1.4%) reporting three shocks and 63 persons (0.9%) reporting four to nine shocks. This indicates that lated 1612 (23%) of the participants had experienced at least one electrical shock during these 26 weeks. 6

The shocks (not persons) are presented in detail in the following tables. The vast majority of the shocks were classified as 'not at all severe' by the participants. The type of electricity was most often alternating current and voltage **a** under 1000 V (table 2A).

During the follow-up period, there was a small decline over time in the reports of the incidence of shocks, and a dip in reporting over Christmas and the new year (around weeks 12-13 of the data collection), because of the holidays (figure 2). In the baseline questionnaire,

Response rate during the 26 weeks of follow-up. Figure 1

several of the participants reported shocks going back some time, but these were omitted from the data if they happened more than 14 days before the questionnaire was completed.

## **Immediate consequences**

Most of the shocks had an entry point in a finger, hand or arm. In most cases, the exit point was also a finger, hand or arm, but many reported that the exit point was unknown. Current passing across the body (in most cases, upper extremity to upper extremity) was less frequent than same side exposure, but again, many did not know, equivalent to reporting of the unknown exit points. Exposure on dry skin was more common than on wet/damp skin (table 2B).

Most of the shocks did not cause any immediate injury, direct or indirect. Table 2C shows consequences reported in the same week as the shock. Only 13 shocks were followed by unconsciousness, whereas 49 shocks led to memory loss; these numbers may be a bit higher than reported, as seven and nine persons, respectively, answered 'do not know' to these questions. In 177 cases those who experienced electrical shocks contacted their doctor/went to hospital, and 68 led to an injury-related absence from work. In 252 cases, shocks caused flashbacks; this exceeds the number of shocks that resulted in physical injury (table 2C).

## DISCUSSION Kev results

Of the 22284 eligible members of the Danish Union of Electricians, 6960 (31%) participated in our cohort đ study, and of these, 61%-81% participated in the 26-week follow-up. During the data collection period, 2356 electrical shocks were experienced by 23.1% of the participants. Of the participants, 1133 (16.3% of participants) experienced one shock and 1223 (6.9% of participants) ta experienced two to nine shocks. The reporting of shocks declined slightly over time. Most of the shocks were reported as 'not severe'. The most frequent type of electricity was alternating current and a voltage below 1000 training, V. The most common entry and exit points were fingers, hands and arms, predominantly dry skin. Surprisingly, many electricians could not determine whether they had current passing across the body, 66% of these because they could not determine the exit point of a shock.

\*Those who reported electrical arc, induction or static electricity were not asked these questions, and included in the missing group.

The immediate consequences reported the same week as an electrical shock were also rare. However, 4.7% resulted in red skin marks, 2.1% resulted in memory loss and 10.7% caused flashbacks to various extents. In 7.5% of cases, healthcare services were contacted, but few shocks resulted in absence from work for more than the same day, and in parallel with this, only a few reported reduced ability to work following a shock.

# Limitations

To the best of our knowledge, the cohort of electrical workers we studied is the first to be monitored for electrical injuries through a prospective design. Despite an intensive campaign to motivate participation, this survey had a relatively low participation rate. This is a possible limitation of the study, especially because the distribution of ages was different among participants and nonparticipants. Attrition during the follow-up phase may also present a problem, as 19% did not respond to any of the follow-up messages, and up to 40% of those who responded to the baseline questions stopped answering Table 2CImmediate consequences of electrical shock(reported in same week as shock) (N=2356)

during the follow-up phase. However, some participants who stopped answering during the data collection returned later. This intermittent pattern of answering

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies

is not as prone to bias as attrition is, if the respondents provided answers both before and after an electrical shock. The decline in the number of shocks over time was greater than the attrition, and we could not find an explanation for this. We examined the response pattern for changes related to reporting a shock, but that was not the case. Participation in the study may have increased awareness of the risk of electrical shock, and this may have led to the decrease.

Participation in the study, especially the baseline survey, which included many questions with various types of response categories, required fundamental reading skills. This may have caused persons who had reading difficulties to be under-represented in the cohort as they might give up on answering. On the other hand, all members of the Danish Union for Electricians are trained electricians, technicians or apprentices who should have sufficient reading skills to participate in this sort of study.

## Interpretation

Only a small proportion of the electrical-shock-related injuries prompted participants to contact a healthcare professional. Most previous studies of electrical injuries are based on hospitalised patients, unusually those in specialised burn units. This study describes a heterogeneous group of electrical shocks, and thus the low proportion of extremely severe shocks reported means that it is not comparable to previous studies in other settings. Since, as far as we know, this study is the first to monitor electrical injuries among electricians through a prospective design with repeated measurements, it is not possible to compare this study with previous work. However, a Norwegian retrospective study of electricians estimated an incidence of 7.6 serious electrical injuries per 100 person-years,<sup>6</sup> which, translated to our design, would result in over 200 serious injuries over 6 months of follow-up. This was not reflected in our findings, in which only 31 shocks were reported as 'quite severe' or 'very severe'. We cannot know whether or not this discrepancy is related to recall bias in the Norwegian study, a different study population, or changes in incidence over time. A retrospective Swedish study of electricians who had experienced at least one electrical shock showed that half of the respondents had experienced an electrical injury at some point in their working life.<sup>21</sup>

# Generalisability

This study may be generalised to other populations of electricians, where the regulations and safety guidelines are in line with the Danish ones. If the participants' risk of electrical shock is consistent with those who did not participate, the incidence and the characteristics of the shocks may be extrapolated to the entire population of Danish electricians. The opportunity to examine the cohort's participants' health before and after an electrical shock may provide results that are generalisable to other contexts, as the participants are compared with themselves before and after an electrical shock, rather than to other populations.

**Contributors** KB, AK, OC and KJN designed the study, discussed its results, strengths and limitations, and approved the final version of the manuscript. KJN programmed the REDCap data collection; KB carried out the initial data management and analysis, wrote the first draft of the manuscript and is responsible for the overall content.

**Funding** This study was supported by the Danish Working Environment Research Fund, grant number 22-2017-09.

Competing interests None declared.

Patient consent for publication Obtained.

Ethics approval The data collection was approved by Central Region on behalf of the Danish Data Protection Agency #1-16-02-139-19. Approval from the Ethics Committee is exempted in Denmark for questionnaire-based data collection.

Provenance and peer review Not commissioned; externally peer reviewed.

Data availability statement Data are available upon reasonable request. Anonymised data are available from the authors on reasonable request.
