Abstract**Objectives**

Leukaemias and lymphomas are among the most prevalent and significant cancers in Australasia and Oceania. This study aims to examine the burden of leukaemias/lymphomas and its temporal trend in Australasia and Oceania from 2010 to 2019.

Design

Epidemiological study

Methods

Data from the Global Burden of Disease (GBD) 2019 was used to examine the burden of leukaemia/lymphoma key subtypes (acute lymphocytic leukaemia (ALL), acute myeloid leukaemia (AML), chronic lymphocytic leukaemia (CLL), chronic myeloid leukaemia (CML), Hodgkin-lymphoma (HL), and non-Hodgkin lymphoma (NHL)) by sex and age group, in terms of incidence, prevalence, disability-adjusted-life-years (DALYs), and deaths. Estimated average percentage changes (EAPCs) were calculated to assess the temporal trends of leukaemia/lymphoma burden (incidence/prevalence/DALYs/deaths) from 2010 to 2019 in Australasia and Oceania.

Results

AML and NHL were the leading causes of leukaemia/lymphoma burden in both regions. From 2010 to 2019, Australasia observed an increasing trend in incidence/prevalence/deaths across most leukaemias/lymphomas and increasing/stable trend in DALYs for AML/CLL/NHL, while Oceania observed increasing trends in incidence/prevalence/DALYs for CLL/NHL and stable trends in all outcomes (except for prevalence (stable)) for AML. Contrasting mortality trends for ALL/CML/HL were observed between the two regions (increasing/stable in Australasia and decreasing in Oceania). Statistically significant

1
2 differences were observed in disease burden trends between sexes, with males experiencing a
3 greater increase (or smaller decrease) in the burden for AML in both regions.

9

10 Conclusions 11

12 Different temporal trends in leukaemia/lymphoma burden observed in two closely situated
13 geographic regions with different socio-demographic indices highlights the necessity for
14 region-specific intervention strategies to enhance the access to innovative disease treatments,
15 reducing leukaemia/lymphoma burden.

30 Strengths and limitations of this study: 31 32

- 33 - We compared the disease burden and temporal trends in two geographically similar
34 regions with differing socio-demographic indices (SDI) and performed a sensitivity
35 analysis using the world standard population, that facilitated the comparison of trends
36 between Australasia and Oceania, and to other regions.
- 37 - Using region-specific data helps reflect disease burden distributions and trends across
38 sexes and age groups more comprehensively and accurately.
- 39 - A direct comparison between Australasia and Oceania is limited due to considerable
40 differences in population distributions and risk factors between the two regions.
- 41 - Analysing aggregate data made it challenging to discern the impact of various
42 exposures to disease outcomes, thus trends should be interpreted with caution.

INTRODUCTION

Haematological malignancies, including leukaemias and lymphomas, arise from the uncontrolled proliferation of cells in the lymphatic or circulatory systems. Based on the Global Burden of Disease, Injuries and Risk Factors Study 2019 (GBD 2019), which provides the most comprehensive estimates of global disease and injury burden to date, haematological malignancies contribute to a considerable proportion of the global disease burden attributed to cancer ¹⁻³. Globally, leukaemias and lymphomas contributed to 11·7 million and 8·2 million disability-adjusted life years (DALYs) in 2019, respectively ². Studies exploring the temporal trend in haematological malignancies across countries using data from the GBD 2019 study have found that over a 30-year period, age-standardised mortality/DALYs have declined, against a background of increasing incident/prevalent burden. However, the distribution of disease burden and temporal trends in leukaemias/lymphomas varies across geographic regions and varying levels of socioeconomic development ^{1 2 4 5}. Differences in disease burden across regions of high/low socioeconomic development were largely attributed to social and environmental factors including poverty, educational attainment, and access to health care ^{1 2 4}. These large disparities in the health care system highlight the need for population-based epidemiological studies in low-and middle-income countries (LMICs) to inform public health policy and healthcare delivery planning ^{1 2 4 5}. Importantly, no studies were identified that explored trends in disease incidence/prevalence or burden for Australasia and Oceania ^{1 2}. Australasia and Oceania may be classified as regions with high and low socioeconomic development, respectively, despite being in the same geographic region of the Pacific ocean ^{3 5}. Furthermore, there are considerable discrepancies in the ethnic composition between Oceania and Australasia which may contribute to disparities in health outcomes ⁶. Therefore, a comparison of leukaemia/lymphoma trends between the two regions may facilitate the

1
2
3 understanding of the impacts attributed to differences in socio-demographic indices (SDIs) on
4 disease occurrence and outcomes.
5
6

7 Hence, this study aims to (1) examine the prevalence, incidence, mortality, and DALYs
8 attributed to leukaemias and lymphomas by sex and age groups and (2) explore the temporal
9 trend in prevalence, incidence, mortality, and DALYs for leukaemias and lymphomas from
10 2010 to 2019 in Oceania and Australasia regions using GBD 2019 data.
11
12

13 METHODS

14 Data source

15 We extracted data from the GBD 2019 and performed a secondary analysis in the current
16 study. All data was collected using Global Health Data Exchange (GHDx) query tool
17 (<http://ghdx.healthdata.org/gbd-results-tool>)^{3,7}. Details pertaining to the collection,
18 processing, and generation of the GBD 2019 study dataset have been described elsewhere^{2,3}.

19 Case definition

20 The definition of leukaemias and lymphomas used in the GBD 2019 study has been defined
21 previously^{2,3}. Leukaemia is typically classified by the type of white blood affected
22 (lymphocytic or myeloid) and disease progression (acute or chronic)⁸. Key leukaemia
23 subtypes include acute lymphocytic leukaemia (ALL), acute myeloid leukaemia (AML),
24 chronic lymphocytic leukaemia (CLL), and chronic myeloid leukaemia (CML)⁸.
25 Lymphomas are categorised based on the type of lymphocyte affected, with key lymphoma
26 subtypes including non-Hodgkin's lymphomas (NHL) and Hodgkin's lymphoma (HL)⁹.

Population and outcome

In this study, we assessed the burden of disease (including prevalence, incidence, deaths, and DALYs) of leukaemias and lymphomas by subtype in Australasia and Oceania from 2010 to 2019. In line with GBD 2019 definitions, Australasia was defined as Australia and New Zealand, and Oceania (18 countries) was defined as American Samoa, Cook Islands, Fiji, Guam, Kiribati, Marshall Islands, Micronesia, Nauru, Niue, Northern Mariana Islands, Palau, Papua New Guinea, Samoa, Solomon Islands, Tokelau, Tonga, Tuvalu, and Vanuatu³.

Patient and public involvement

Patients and/or the public were not involved in the design, or conduct, or reporting, or dissemination plans of this research.

Statistical analysis

A descriptive analysis was performed to characterise the regional burden of leukaemias and lymphomas (by subtype). The number of prevalent and incident cases, deaths, and DALYs were used to derive age-standardised rates (ASRs) (per 100 000 population) in Australasia and Oceania from 2010 to 2019. ASRs were calculated to exclude the impact of age structure on overall population prevalence, incidence, mortality, and DALYs as the number of cases, deaths and DALYs of cancers varies greatly across different age groups^{1,7}. The ASR per 100 000 population is the weighted-average of age-group-specific rates, that is,
$$\text{ASR} = \frac{\sum_{i=1}^A a_i w_i}{\sum_{i=1}^A w_i}$$
 × 100 000, where a_i is the age-group specific rate i and w_i is the weight of age group i of the population⁷. For the purposes of the base-case analysis, the number of outcomes (incidence, prevalence, deaths or DALYs) occurring for each five-year age group (< 5 years to 85+), were divided by the number of individuals estimated in each age group for

Australasia (or Oceania) to estimate age-group-specific rates for each year (a_i). This was multiplied by the proportional distribution (w_i) of individuals in each age group to estimate the ASR.

The estimated average percentage change (EAPC) in ASRs was estimated to assess temporal trends in prevalence, incidence, mortality, and DALYs of leukaemias and lymphomas (by subtype) over a 10-year period (2010 to 2019, inclusive). EAPCs were calculated through generalised linear regression modelling (GLM) with a gaussian family and log-link to estimate trends: $y = \alpha + \beta * x + \varepsilon$, where y is $\ln(\text{ASR})$ and x is the calendar year. The EAPC was expressed as $100 * (e^\beta - 1)$ ¹. If the estimated β -coefficient and its 95% CI were both positive, it indicated an upward trend in ASR, whereas a negative β -coefficient and its 95% CI indicated a downward trend in ASR^{1,7}. Otherwise, the temporal trend in outcomes were assumed to be stable. P-values <0.05 were considered statistically significant.

All calculations were performed using Stata 17.0 statistical software (Stata Corp, College Station, TX).

Sensitivity analysis

As described above, ASRs were calculated in our base case analysis based on the estimated population size across 5-year age groups for Australasia and Oceania. To allow for comparability between trends in Australasia and Oceania, a sensitivity analysis was performed by applying the world standard population weights to age-group-specific rates for key outcomes estimated in our base case analysis¹⁰. Results of the sensitivity analysis are presented in Appendix B.

RESULTS

Table 1 summarises the leukaemia and lymphoma burden in terms of incidence, prevalence, DALYs, and deaths across Australasia and Oceania and associated temporal trends. Table 2 summarises trends in leukaemia and lymphoma burden by sex. Figures 1 summarises the leukaemia and lymphoma burden in terms of incidence, prevalence, DALYs, and deaths across Australasia and Oceania, by age group, and sex in 2019, respectively.

[Table 1 around here]

[Table 2 around here]

[Figure 1 around here]

Overview of disease burden

Leukaemia and lymphoma burden in Australasia

Across Australasia, the greatest contributor to incidence of leukaemia and lymphoma in 2019 was CLL (ASR: 5·22 per 100 000) and NHL (ASR: 19·06 per 100 000), respectively. ALL accounted for the largest share in paediatric leukaemia incidence, whereas CLL accounted for the largest share of incident cases for adult leukaemias. NHL (ASRs: 161·68 DALYs and 8·02 deaths per 100 000), AML (ASRs: 89·01 DALYs and 4·15 deaths per 100 000), followed by CLL, contributed to the greatest proportion in terms of DALYs and mortality burden in 2019. NHL was the most prevalent haematological cancer in 2019. Following stratification of disease burden by five-year age band and sex, the incidence, prevalence, DALY, and mortality rates across five-year age groups generally increased with ascending age across leukaemia/lymphoma subtypes for Australasia (see Figure 1 and Appendix A).

1
2 Age-specific incidence/prevalence and DALY rates for ALL and HL followed a bimodal
3 pattern.

5
6
7
8
9

10 Leukaemia and lymphoma burden in Oceania 11

12 In Oceania, AML and ALL drove leukaemia burden (incident/prevalent/DALYs/deaths) and
13 NHL was the key contributor to the incident lymphoma burden (ASR: 1·08 per 100 000) in
14 2019. HL (ASR: 0·81 per 100 000) drove prevalent lymphoma burden. Regarding the burden
15 of disease (DALYs/deaths), AML (ASRs: 49·16 DALYs and 0·91 deaths per 100 000) and
16 NHL (ASRs: 38·30 DALYs and 0·98 deaths per 100 000) were the largest contributors in
17 2019. Disease burden across age-groups and sexes for Oceania were broadly comparable with
18 Australasia. That is, incident/prevalent burden, as well as DALYs/deaths, increased with
19 increasing age and for male sex. (Table 1)

34 Temporal trends in leukaemia and lymphomas (base-case analysis) 35

36 *Australasia* 37

38 The incidence and prevalence of haematological malignancies across Australasia increased
39 significantly over a 10-year period (2010 to 2019, inclusive) ($P<0\cdot001$). Temporal increasing
40 trends in incident/prevalent cases were largely driven by CLL, ALL, and CML (EAPCs
41 ranging from 2·16% to 2·87%) (all $P<0\cdot001$). Notably, the EAPC and associated 95% CI for
42 leukaemia and lymphoma incidence was broadly comparable between sexes with the
43 exception of CML and HL (greater for females), and AML (greater for males). Regarding
44 prevalent burden, EAPCs in males were found to be higher for AML, and lower for HL
45 relative to females.
46
47

48 DALY burden (per 100 000) increased significantly for CLL (EAPC: 1·74%) and AML
49 (EAPC: 1·15%) over time, whereas significant reductions in DALY burden attributed to
50

1
2
3 CML (EAPC: -1·23%), HL (EAPC: -0·40%) and ALL (EAPC: -0·36%) were observed (all
4 P<0·05). DALY burden attributed to NHL remained stable over time (both sexes). Male sex
5 drove temporal reductions in DALYs (ALL, CML, and HL) whereas the only significant
6 reduction in DALY burden for females was for HL. Although AML and CLL DALY burden
7 increased for both sexes, the EAPC estimated for AML was of greater magnitude for males
8 relative to females (EAPCs: 1·51% versus 0·69%). Lastly, mortality from
9 leukaemias/lymphomas significantly increased over time (EAPCs ranging from 0·75% for
10 ALL to 2·11% for CLL), with the exception of CML and HL (stable). Overall, trends in
11 mortality were comparable between sexes, with the exception of greater increases in
12 mortality over time for AML and NHL for males compared with females (EAPCs: 2·55%
13 versus 1·46%). (Table 2)

Oceania

The increased incidence in CLL (EAPC: 1·38%) and NHL (EAPC: 0·92%) was balanced with significantly decreases in ALL (EAPC: -0·45%) and CML (EAPC: -0·58%) incidence. The overall stable trend in HL incidence over time was a result of opposing temporal trends in males (decreasing with EAPC: -0·19%) and females (increasing with EAPC: 0·31%). The overall incidence of AML was stable, driven by females (stable), despite increasing over time for males (EAPC: 0·17%). Although CLL incidence increased over time for both sexes, the EAPC was higher for females. Significant increases in the prevalence of NHL (EAPC: 3·24%), CLL (EAPC: 1·99%) and HL (EAPC: 0·68%) were balanced with reductions in the prevalence of CML (EAPC: -0·76%), ALL (EAPC: -0·56%) and AML (EAPC: -0·21%). Although temporal trends for ALL, CML CLL, HL and NHL prevalence were in the same direction across both sexes (decreasing for ALL/CML and increasing for CLL/HL/NHL), the decline in AML prevalence was driven by females (stable for males). Ultimately, the overall

1
2 incidence and prevalence of leukaemias/lymphomas across Oceania had remained stable over
3 time.
4

5 In terms of disease burden, modest but statistically significant annual reductions in DALYs
6 were observed for ALL, CML and HL (range in EAPCs: -0·55% for HL to -0·88% for CML)
7 across both sexes, whereas the DALY burden attributed to CLL (EAPC: 0·92%) and NHL
8 increased over time (EAPC: 0·26%) (all P<0·001). AML DALY burden over time was stable,
9 and largely driven by males (stable in males while decreasing in females). Lastly, with the
10 exception of AML, CLL and NHL, the mortality burden attributed to leukaemias/lymphomas
11 declined over time (range in EAPCs: -0·48% for CML to -0·35% for HL). Between 2010 and
12 2019, significant declines in mortality burden attributed to ALL and CML, and significantly
13 increased CLL mortality, were estimated across both sexes. However, AML mortality burden
14 increased significantly for males, and remained stable over time for females. Furthermore, the
15 increase in CLL mortality over time was greater for females relative to males. Regarding
16 lymphoma subtypes and sex, the overall decline in HL mortality was driven by males (stable
17 for females), while NHL mortality increased over time for both sexes. (Table 2)

40 DISCUSSION

41 Our study is the first to report trends across a variety of outcomes between Australasia and
42 Oceania over a 10-year period (2010 – 2019, inclusive) in which considerable changes in
43 clinical practice occurred for cancer ¹⁻³. Discrepancies in disease burden (ASRs) across
44 regions were observed, which may be attributed to differences in age distribution ¹⁻¹¹ as well
45 as differences in health care and cancer surveillance/registration systems between high-SDI
46 and low-SDI countries ¹⁻². NHL was the key contributor to overall disease burden
47 (DALYs/deaths) across both Australasia and Oceania. Despite the high relative incidence of
48 AML, prevalence remained low across Australasia and likely reflects poor patient survival
49
50
51
52
53
54
55
56
57
58
59
60

(relative 5-year survival rate of 27%)¹². In contrast, the considerable DALY/mortality burden attributed to NHL likely reflects on high disease incidence, as 5-year survival for patients with NHL is considerably higher relative to AML^{12 13}. Notably, recent advances in the treatment of NHL and AML have contributed to improved patient survival, including the development of immune-based cellular and antibody therapies, and small molecule inhibitors^{14 15}. However, despite improved management of patients with leukaemias/lymphomas in Australasia, the considerable disease burden for both NHL and AML warrants further research to address unmet needs.

Upon stratification to explore the distribution of age (5-year age group) and sex (male/female) burden, age-specific leukaemia/lymphoma burden generally increased with increasing age and for males across both regions. Notably, disparate patient outcomes were identified between sexes for both regions with respect to AML; that is, disease burden (DALYs/deaths) was predominately borne by males despite incidence/prevalence rates for AML being similar among females in Australasia and Oceania. This is in line with other studies exploring patient outcomes in AML, and has been attributed to differences in biological risk factors, lifestyle, or environmental factors, and differences in disease treatment and management^{16 17}. Issues with health systems reporting, differential access to health services between females and males, differences in age distribution, and greater gender inequality have been implicated in contributing to discrepancies in disease burden between sexes across low-and high-SDI countries^{15 18}. However, further studies are recommended to establish and address sex-based drivers of leukaemia/lymphoma burden in countries with low-or-middle SDIs^{15 7 18}.

Based on trend analysis (EAPCs), leukaemia/lymphoma incidence/prevalence/mortality increased significantly over a 10-year period across Australasia (excepting stable mortality inCML and HL). Following stratification by sex, the trend of increasing incident/prevalent

burden was maintained across both sexes, with the exception of CML incidence which was stable for males. The trend of increasing mortality for AML was driven by male sex, whereas mortality trends across leukaemias/lymphomas were broadly comparable between sexes (excepting CML and HL). This is consistent with existing studies exploring the leukaemia/lymphoma burden for high-SDI countries between sexes [17](#). That is, the risks for attributable leukaemia/lymphoma burden were slightly different between sexes, with tobacco use and occupational exposure to carcinogens being more commonly observed in males and increased high body mass index (BMI) being among the top five risk exposure in females [19](#). Notably, significant reductions in the CML/HL/ALL DALY burden were observed and NHL DALY burden remained stable over time. This is reflective of improved outcomes due to changes in patient management and treatment across Australasia [20-23](#). However, the discrepancy between reductions/stable DALY burden (ALL and NHL) against mortality and incidence/prevalence increases over time may highlight disparate outcomes across age groups [20 21 24 25](#). ALL follows a bimodal age distribution, with the number of incident/prevalent cases peaking during early childhood and later adulthood (≥ 50 years), while NHL cases and the risk of mortality (ALL and NHL) increase with increasing age [16 26 27](#). Therefore, it is likely that improved disease management and treatment over time have led to a greater reduction in disease burden (DALYs) for younger patients relative to the change in mortality burden among older patients [20](#). This is supported by recent studies exploring ALL and NHL outcomes across Australasia, which found improvements in the management or treatment of disease coincided with greater gains in survival outcomes for younger relative to older patients [20 21 24 25 28](#).

In comparison with Australasia, the overall incident/prevalent burden across Oceania remained stable over time. Differing trends between regions highlights potential differences in exposure to environmental and lifestyle risk factors such as benzene exposure, tobacco

1
2
3 consumption, BMI and metabolic disease, and the disparity in health infrastructure and
4 resources allocated for the detection for leukaemia/lymphomas between the two regions [29 30](#).
5
6 Contrasting mortality trends for ALL/CML/HL were observed in the two regions
7 (increasing/stable in Australasia versus decreasing in Oceania) may be attributed to the
8 relatively older population residing in Australasia [11](#). Different trends were observed in AML
9 burden (incidence/prevalence/DALYs/deaths) across males/females. Notably, a *stable*
10 DALY/prevalent AML burden over time against a background of *increasing*
11 mortality/incident burden time for male patients with AML across Oceania was observed. In
12 contrast to AML trends across outcomes in Australia (all increased), this likely reflects a
13 higher risk of mortality relative to patients with AML in Oceania, and suggests potential
14 disparities in access to treatment, particularly novel treatments and clinical trials in AML,
15 between the two regions [24](#). This aligns with studies exploring the association between
16 DALY burden in cancers, and SDI [24](#). That is, DALYs vary with socioeconomic
17 development, with improved patient survival increasing years-lived with disability (and
18 subsequently, DALYs) for regions with a high-SDI [24](#). Although the overall burden
19 (DALY/deaths) of the majority of leukaemias/lymphomas remained stable or slightly
20 decreased over time, the DALY/death burden for CLL and NHL increased across Oceania for
21 both sexes. In comparison with Australasia, the EAPC for CLL trends (incidence/deaths) was
22 greater for females relative to males in Oceania. Furthermore, female NHL burden
23 (DALYs/deaths) had remained stable over time in Australia, while increasing in Oceania.
24 That is, the discrepancy in trend in CLL/NHL burden suggests potential sex disparities in the
25 management or treatment of disease in these regions [15 30](#).
26
27 Lastly, discrepancies in temporal trends were identified in sensitivity analyses using the
28 world standard population. Notably, disease burden attributed to AML and NHL reduced
29 across both regions in comparison with base-case estimates. This is likely attributed to the
30

1
2 variation in population structure in each region, which differs from the standard population ³
3
4 ¹⁰. As sex and age are associated with cancer outcomes, it is possible that EAPCs estimated
5 using the standard population would inadequately capture the impact of region-specific
6 differences in age/sex, and ultimately, overestimate patient survival trends.
7
8

9
10 A key strength of our study lies in using data from the GBD 2019 study, which provides the
11 latest regional epidemiological distributions and trends of leukaemias and lymphomas ³.
12
13 Besides, the comprehensive analysis of trends across a variety of key outcomes facilitates an
14 understanding of the impacts of changes in patient management/treatment on patient
15 outcomes and potential areas of unmet need. Furthermore, disease burden and temporal
16 trends in our study were estimated based on region-specific population, which may better
17 reflect disease burden distribution and trend across age groups and sexes more
18 comprehensively and accurately, particularly when regional population structure is
19 incomparable to the world standard population. Lastly, restricting the analysis to two
20 geographically similar regions with differing SDI, and performing a sensitivity analysis using
21 the world standard population facilitates the comparison of trends between the two regions
22 (base-case), and to other regions or nations at the global level (sensitivity analysis).
23
24

25 However, several limitations to our analyses warrant mention. Limitations associated with
26 GBD 2019 data have been described previously ¹⁻⁴. In brief, it is likely that key outcomes for
27 Oceania were underestimated, as the capacity to collect reliable data on haematological
28 malignancies is often lacking in low-SDI regions. However, this does not considerably
29 change our findings of disparities in disease burden and temporal trends observed between
30 Australasia and Oceania, as well as between male/female sex. Second, GBD data includes
31 disease classifications by sex and age groups, but lacks ethnicity data, which limits the
32 analysis of genetic susceptibility to disease. Third, a direct comparison between Australasia
33 and Oceania could be difficult as there are considerable differences in the population

2
3 distribution and risk factors between the two regions [1-4](#). As such, to explore the potential
4 impacts attributed to age and sex distribution, our analyses used both region-specific
5 populations (base-case) and standard population weights (sensitivity analyses) to explore
6 changes in age-standardised outcomes. Fourth, it was not possible to discern the impact of
7 various exposures on disease outcomes using aggregate data; as such, trends should be
8 interpreted with caution due to potential confounding [1-4](#). Lastly, it was not possible to capture
9 the impacts of the COVID-19 pandemic on leukaemia/lymphoma burden using GBD 2019
10 data [2](#) [3](#) [31](#).

11
12 Ultimately, our findings highlight disparities in the management and treatment of
13 haematological malignancies based on SDI and sex. Despite the emergence of novel therapies
14 and improved treatment/management over time, the consistent and considerable burden of
15 AML and NHL in both regions warrants further research to mitigate the gap attributed to
16 socioeconomic disadvantage. Further research is also recommended to explore factors that
17 contribute to disparate outcomes for sex (male/female).

38 CONCLUSION

39
40 This study captures the disease burden of leukaemias/lymphomas and its temporal trends in
41 two closely situated geographic regions with different SDI. The considerable disparity in
42 disease burden observed between the two regions suggests the need for early diagnosis and
43 better management strategies tailored to each region. Further study is required to explore the
44 underlying factors behind the epidemiological trends of different leukaemia and lymphoma
45 subtypes in each region and the male predominance in the majority of leukaemia and
46 lymphoma burden of disease.

Ethics and dissemination

Ethics approval is not required for this study as the study involve information freely available in an open source.

Patient consent

Non patient consent required.

Data availability statement

All data relevant to the study are included in the article and uploaded as supplementary information.

1 1 Abstract

2 2 Objectives

3 Leukaemias and lymphomas are among the most prevalent and significant cancers in
4 Australasia and Oceania. This study aims to examine the burden of leukaemias/lymphomas
5 and its temporal trend in Australasia and Oceania from 2010 to 2019.

6 6 Design

7 Epidemiological study

8 8 Methods

9 Data from the Global Burden of Disease (GBD) 2019 was used to examine the burden of
10 leukaemia/lymphoma key subtypes (acute lymphocytic leukaemia (ALL), acute myeloid
11 leukaemia (AML), chronic lymphocytic leukaemia (CLL), chronic myeloid leukaemia
12 (CML), Hodgkin-lymphoma (HL), and non-Hodgkin lymphoma (NHL)) by sex and 5-year
13 age groups (from <5yrs to 85yrs+), in terms of incidence, prevalence, disability-adjusted-life-
14 years (DALYs), and deaths. Estimated average percentage changes (EAPCs) were calculated
15 to assess the temporal trends of leukaemia/lymphoma burden
16 (incidence/prevalence/DALYs/deaths) from 2010 to 2019 in Australasia and Oceania.

17 17 Results

18 AML and NHL were the leading causes of leukaemia/lymphoma burden in both regions.
19 Age-standardised rates (ASRs) for AML vs NHL in Australasia were: incidence 4.72 vs.
20 19.06, DALYs 89.01 vs. 161.68, and deaths 4.15 vs. 8.02 per 100 000 population. ASRs for
21 AML vs. NHL in Oceania were: incidence 1.36 vs 1.08, DALYs 49.16 vs 38.3, and deaths
22 0.94 vs. 0.98 per 100 000 population. From 2010 to 2019, Australasia observed an increasing
23 trend in incidence/prevalence/deaths across most leukaemias/lymphomas and
24 increasing/stable trend in DALYs for AML/CLL/NHL, while Oceania observed increasing
25 trends in incidence/prevalence/DALYs for CLL/NHL and stable trends in all outcomes
26 (except for prevalence (stable)) for AML. Contrasting mortality trends for ALL/CML/HL
27 were observed between the two regions (increasing/stable in Australasia and decreasing in
28 Oceania). Statistically significant differences were observed in disease burden trends between
29 sexes, with males experiencing a greater increase (or smaller decrease) in the burden for
30 AML in both regions.

31

32 32 Conclusions

1
2
3 1 Different temporal trends in leukaemia/lymphoma burden observed in two closely situated
4 2 geographic regions with different socio-demographic indices highlights the necessity for
5 3 region-specific intervention strategies to enhance the access to innovative disease treatments,
6 4 reducing leukaemia/lymphoma burden.

1
2 **Strengths and limitations of this study:**

- 3 - We compared the disease burden and temporal trends in two geographically similar
4 regions with differing socio-demographic indices (SDI) and performed a sensitivity
5 analysis using the world standard population, that facilitated the comparison of trends
6 between Australasia and Oceania, and to other regions.
7
8 - Using region-specific data helps reflect disease burden distributions and trends across
9 sexes and age groups more comprehensively and accurately.
10 - A direct comparison between Australasia and Oceania is limited due to considerable
11 differences in population distributions and risk factors between the two regions.
12
13 - Analysing aggregate data made it challenging to discern the impact of various
14 exposures to disease outcomes, thus trends should be interpreted with caution.

1 1 INTRODUCTION

2 2 Haematological malignancies, including leukaemias and lymphomas, arise from the
3 3 uncontrolled proliferation of cells in the lymphatic or circulatory systems. Based on the
4 4 Global Burden of Disease, Injuries and Risk Factors Study (GBD) 2019, which provides the
5 5 most comprehensive estimates of global disease and injury burden to date, haematological
6 6 malignancies contribute to a considerable proportion of the global disease burden attributed
7 7 to cancer¹⁻³. Globally, leukaemias and lymphomas contributed to 11·7 million and 8·2
8 8 million disability-adjusted life years (DALYs) in 2019, respectively². Studies exploring the
9 9 temporal trend in haematological malignancies across countries using data from the GBD
10 10 2019 study have found that over a 30-year period, age-standardised mortality/DALYs have
11 11 declined, against a background of increasing incident/prevalent burden. However, the
12 12 distribution of disease burden and temporal trends in leukaemias/lymphomas varies across
13 13 geographic regions and varying levels of socioeconomic development^{1 2 4 5}. Differences in
14 14 disease burden across regions of high/low socioeconomic development were largely
15 15 attributed to social and environmental factors including poverty, educational attainment, and
16 16 access to health care^{1 2 4}. These large disparities in the health care system highlight the need
17 17 for population-based epidemiological studies in both high and low-and middle-income
18 18 countries (LMICs) to inform public health policy and healthcare delivery planning^{1 2 4 5}.

19 19 Importantly, no studies have systematically explored trends in disease incidence/prevalence
20 20 or burden of leukaemias/lymphomas for Australasia and Oceania^{1 2}. Epidemiological studies
21 21 comparing these two Pacific regions are particularly beneficial given the considerable
22 22 socioeconomic, cultural and ethnic differences between these regions³. As such, a
23 23 comparison of contemporaneous leukaemia/lymphoma trends between Australasia and
24 24 Oceania may facilitate the understanding of healthcare disparities, the impacts of
25 25 sociodemographic factors on disease occurrence and outcomes, and the role of healthcare
26 26 infrastructure in managing these cancers. Moreover, although data on leukaemia and
27 27 lymphoma burden are often reported in regional cancer registry reports, and also publicly
28 28 available in the GBD data set, research specifically focusing on trends in haematological
29 29 malignancies in Australasia and Oceania are scarce⁶⁻⁹. This gap in the literature underscores
30 30 the importance of region-specific research to better understand these trends and inform
31 31 policies tailored to these regions. Ultimately, such a study would inform future research,
32 32 public healthcare planning strategies, and policies aimed at reducing the burden related to

1 1 leukaemia/lymphoma in Australasia and Oceania – the two regions populated with
2 2 Indigenous people, closely geographically located but varied sociodemographic factors.
3 3 Hence, this study aims to (1) examine the prevalence, incidence, mortality, and DALYs
4 4 attributed to leukaemias and lymphomas by sex and age groups and (2) explore the temporal
5 5 trend in these metrics for leukaemias and lymphomas from 2010 to 2019 in Oceania and
6 6 Australasia regions using GBD 2019 data.

7

15 8 METHODS

16 9 Data source

17 10 We extracted data from the GBD 2019 and performed a secondary analysis in the current
18 11 study¹⁰. All data was collected using Global Health Data Exchange (GHDx) query tool
19 12 (<http://ghdx.healthdata.org/gbd-results-tool>)^{3 11}. Details pertaining to the collection,
20 13 processing, and generation of the GBD 2019 study dataset have been described elsewhere^{2 3}.

21 14 Case definition

22 15 The definition of leukaemias and lymphomas used in the GBD 2019 study has been defined
23 16 previously using International Classification of Diseases (ICD) codes (Appendix A)^{2 3}.
24 17 Leukaemia is typically classified by the type of white blood affected (lymphocytic or
25 18 myeloid) and disease progression (acute or chronic)¹². Key leukaemia subtypes include acute
26 19 lymphocytic leukaemia (ALL), acute myeloid leukaemia (AML), chronic lymphocytic
27 20 leukaemia (CLL), and chronic myeloid leukaemia (CML)¹². Lymphomas are categorised
28 21 based on the type of lymphocyte affected, with key lymphoma subtypes including non-
29 22 Hodgkin's lymphomas (NHL) and Hodgkin's lymphoma (HL)¹³.

30 23 Population and outcome

31 24 In this study, we assessed the burden of disease (including prevalence, incidence, deaths, and
32 25 DALYs) of leukaemias and lymphomas by subtype in Australasia and Oceania from 2010 to
33 26 2019. In line with GBD 2019 definitions, Australasia was defined as Australia and New
34 27 Zealand, and Oceania (18 countries) was defined as American Samoa, Cook Islands, Fiji,
35 28 Guam, Kiribati, Marshall Islands, Micronesia, Nauru, Niue, Northern Mariana Islands, Palau,
36 29 Papua New Guinea, Samoa, Solomon Islands, Tokelau, Tonga, Tuvalu, and Vanuatu³.

37 30
38 31
39 32

1 1 Patient and public involvement

2 2 Patients and/or the public were not involved in the design, or conduct, or reporting, or
3 3 dissemination plans of this research.

4
5 5 Statistical analysis

6 6 A descriptive analysis was performed to characterise the regional burden of leukaemias and
7 7 lymphomas (by subtype). The number of prevalent and incident cases, deaths, and DALYs
8 8 were used to derive age-standardised rates (ASRs) (per 100 000 population) in Australasia
9 9 and Oceania from 2010 to 2019. ASRs were calculated to exclude the impact of age structure
10 10 on overall population prevalence, incidence, mortality, and DALYs as the number of cases,
11 11 deaths and DALYs of cancers varies greatly across different age groups^{1 11}. The ASR per
12 12 100 000 population is the weighted-average of age-group-specific rates, that is, ASR =
13 13 $\frac{\sum_{i=1}^A a_i w_i}{\sum_{i=1}^A w_i} \times 100 000$, where a_i is the age-group specific rate i and w_i is the weight of age
14 14 group i of the population¹¹. For the purposes of the base-case analysis, the number of
15 15 outcomes (incidence, prevalence, deaths or DALYs) occurring for each five-year age group
16 16 (< 5 years to 85+), were divided by the number of individuals estimated in each age group for
17 17 Australasia (or Oceania) to estimate age-group-specific rates for each year (a_i). This was
18 18 multiplied by the proportional distribution (w_i) of individuals in each age group to estimate
19 19 the ASR.

20 20 The estimated average percentage change (EAPC) in ASRs was estimated to assess temporal
21 21 trends in prevalence, incidence, mortality, and DALYs of leukaemias and lymphomas (by
22 22 subtype) over a 10-year period (2010 to 2019, inclusive). EAPCs were calculated through
23 23 generalised linear regression modelling (GLM) with a gaussian family and log-link to
24 24 estimate trends: $y = \alpha + \beta * x + \varepsilon$, where y is $\ln(\text{ASR})$ and x is the calendar year. The EAPC
25 25 was expressed as $100 * (e^\beta - 1)$ ¹. If the estimated β -coefficient and its 95% CI were both
26 26 positive, it indicated an upward trend in ASR, whereas a negative β -coefficient and its 95%
27 27 CI indicated a downward trend in ASR^{1 11}. Otherwise, the temporal trend in outcomes were
28 28 assumed to be stable. P-values <0·05 were considered statistically significant.

29 29 All calculations were performed using Stata 17.0 statistical software (Stata Corp, College
30 30 Station, TX).

31

1
2 1 **Sensitivity analysis**

3
4 2 As described above, ASRs were calculated in our base case analysis based on the estimated
5 population size across 5-year age groups for Australasia and Oceania. To allow for
6 comparability between trends in Australasia and Oceania, a sensitivity analysis was
7 performed by applying the world standard population weights to age-group-specific rates for
8 key outcomes estimated in our base case analysis¹⁴.
9
10

11 7
12 8 **RESULTS**

13 9 The leukaemia and lymphoma burden in terms of incidence, prevalence, DALYs, and deaths
14 across Australasia and Oceania and associated temporal trends are summarised in Table 1 and
15 2, respectively. Table 3 and 4 summarises trends in leukaemia and lymphoma burden by sex.
16 Figures 1 summarises the leukaemia and lymphoma burden in terms of incidence, prevalence,
17 DALYs, and deaths across Australasia and Oceania, by age group, and sex in 2019,
18 respectively. Figure 2 illustrates the trends in leukaemia and lymphoma burden by subtypes
19 during the period 2010-2019.

1 1 Overview of disease burden

2 2 Leukaemia and lymphoma burden in Australasia

3 3 Across Australasia, the greatest contributor to incidence of leukaemia and lymphoma in 2019
4 4 was CLL (ASR: 5·22 per 100 000) and NHL (ASR: 19·06 per 100 000), respectively. ALL
5 5 accounted for the largest share in paediatric leukaemia incidence, whereas CLL accounted for
6 6 the largest share of incident cases for adult leukaemias. NHL (ASRs: 161·68 DALYs and
7 7 8·02 deaths per 100 000), AML (ASRs: 89·01 DALYs and 4·15 deaths per 100 000),
8 8 followed by CLL, contributed to the greatest proportion in terms of DALYs and mortality
9 9 burden in 2019. NHL was the most prevalent haematological cancer in 2019. Following
10 10 stratification of disease burden by five-year age band and sex, the incidence, prevalence,
11 11 DALY, and mortality rates across five-year age groups generally increased with ascending
12 12 age across leukaemia/lymphoma subtypes for Australasia (see Figure 1 and Appendix B).
13 13 Age-specific incidence/prevalence and DALY rates for ALL and HL followed a bimodal
14 14 pattern.

15

16 16 Leukaemia and lymphoma burden in Oceania

17 17 In Oceania, AML and ALL drove leukaemia burden (incident/prevalent/DALYs/deaths) and
18 18 NHL was the key contributor to the incident lymphoma burden (ASR: 1·08 per 100 000) in
19 19 2019. HL (ASR: 0·81 per 100 000) drove prevalent lymphoma burden. Regarding the burden
20 20 of disease (DALYs/deaths), AML (ASRs: 49·16 DALYs and 0·91 deaths per 100 000) and
21 21 NHL (ASRs: 38·30 DALYs and 0·98 deaths per 100 000) were the largest contributors in
22 22 2019. Disease burden across age-groups and sexes for Oceania were broadly comparable with
23 23 Australasia. That is, incident/prevalent burden, as well as DALYs/deaths, increased with
24 24 increasing age and for male sex. (Table 1)

25

26 26 Temporal trends in leukaemia and lymphomas (base-case analysis)

27 27 Australasia

28 28 The incidence and prevalence of haematological malignancies across Australasia increased
29 29 significantly over a 10-year period (2010 to 2019, inclusive) ($P<0\cdot001$). Temporal increasing
30 30 trends in incident/prevalent cases were largely driven by CLL, ALL, and CML (EAPCs
31 31 ranging from 2·16% to 2·87%) (all $P<0\cdot001$). Notably, the EAPC and associated 95% CI for
32 32 leukaemia and lymphoma incidence was broadly comparable between sexes with the
33 33 exception of CML and HL (greater for females), and AML (greater for males). Regarding

1 prevalent burden, EAPCs in males were found to be higher for AML, and lower for HL
2 relative to females.
3 DALY burden (per 100 000) increased significantly for CLL (EAPC: 1·74%) and AML
4 (EAPC: 1·15%) over time, whereas significant reductions in DALY burden attributed to
5 CML (EAPC: -1·23%), HL (EAPC: -0·40%) and ALL (EAPC: -0·36%) were observed (all
6 P<0·05). DALY burden attributed to NHL remained stable over time (both sexes). Male sex
7 drove temporal reductions in DALYs (ALL, CML, and HL) whereas the only significant
8 reduction in DALY burden for females was for HL. Although AML and CLL DALY burden
9 increased for both sexes, the EAPC estimated for AML was of greater magnitude for males
10 relative to females (EAPCs: 1·51% versus 0·69%). Lastly, mortality from
11 leukaemias/lymphomas significantly increased over time (EAPCs ranging from 0·75% for
12 ALL to 2·11% for CLL), with the exception of CML and HL (stable). Overall, trends in
13 mortality were comparable between sexes, with the exception of greater increases in
14 mortality over time for AML and NHL for males compared with females (EAPCs: 2·55%
15 versus 1·46%). (Table 2)

16 17 *Oceania*

18 The increased incidence in CLL (EAPC: 1·38%) and NHL (EAPC: 0·92%) was balanced
19 with significantly decreases in ALL (EAPC: -0·45%) and CML (EAPC: -0·58%) incidence.
20 The overall stable trend in HL incidence over time was a result of opposing temporal trends
21 in males (decreasing with EAPC: -0·19%) and females (increasing with EAPC: 0·31%). The
22 overall incidence of AML was stable, driven by females (stable), despite increasing over time
23 for males (EAPC: 0·17%). Although CLL incidence increased over time for both sexes, the
24 EAPC was higher for females. Significant increases in the prevalence of NHL (EAPC:
25 3·24%), CLL (EAPC: 1·99%) and HL (EAPC: 0·68%) were balanced with reductions in the
26 prevalence of CML (EAPC: -0·76%), ALL (EAPC: -0·56%) and AML (EAPC: -0·21%).
27 Although temporal trends for ALL, CML CLL, HL and NHL prevalence were in the same
28 direction across both sexes (decreasing for ALL/CML and increasing for CLL/HL/NHL), the
29 decline in AML prevalence was driven by females (stable for males). Ultimately, the overall
30 incidence and prevalence of leukaemias/lymphomas across Oceania had remained stable over
31 time.

32 In terms of disease burden, modest but statistically significant annual reductions in DALYs
33 were observed for ALL, CML and HL (range in EAPCs: -0·55% for HL to -0·88% for CML)
34 across both sexes, whereas the DALY burden attributed to CLL (EAPC: 0·92%) and NHL

1 increased over time (EAPC: 0·26%) (all P<0·001). AML DALY burden over time was stable,
2 and largely driven by males (stable in males while decreasing in females). Lastly, with the
3 exception of AML, CLL and NHL, the mortality burden attributed to leukaemias/lymphomas
4 declined over time (range in EAPCs: -0·48% for CML to -0·35% for HL). Between 2010 and
5 2019, significant declines in mortality burden attributed to ALL and CML, and significantly
6 increased CLL mortality, were estimated across both sexes. However, AML mortality burden
7 increased significantly for males, and remained stable over time for females. Furthermore, the
8 increase in CLL mortality over time was greater for females relative to males. Regarding
9 lymphoma subtypes and sex, the overall decline in HL mortality was driven by males (stable
10 for females), while NHL mortality increased over time for both sexes. (Table 2)

12 Sensitivity analysis

13 Results of the sensitivity analysis are presented in Appendix C. While broadly comparable
14 with base-case estimates, discrepancies in the direction of the trend (decreasing, stable or
15 increasing) over time were identified for 20 (42%) out of 48 estimable trends following
16 application of the World Standard population.

18 DISCUSSION

19 Our study is the first to report trends across a variety of outcomes between Australasia and
20 Oceania over a 10-year period (2010 – 2019, inclusive) in which considerable changes in
21 clinical practice occurred for cancer¹⁻³. Discrepancies in disease burden (as indicated by
22 ASRs) across regions, and across age groups and sexes were observed. This is likely
23 attributed to differences in age distribution¹⁻¹⁵, differences in health care and cancer
24 surveillance/registration systems, as well as differences in accessing the social determinants
25 of health between high socio-demographic indices (SDI) and low-SDI countries¹⁻². For
26 example, recent advances in the treatment of NHL and AML have contributed to improved
27 patient survival, including the development of immune-based cellular and antibody therapies,
28 and small molecule inhibitors¹⁵⁻¹⁶. However, despite improved management of patients with
29 leukaemias/lymphomas in Australasia, the considerable disease burden for both NHL and
30 AML warrants further research to address unmet need. Moreover, NHL contributed the most
31 to mortality burden in Oceania, which may highlight issues in the effective management of
32 NHL in the region. Upon stratification to explore the distribution of age (5-year age group)
33 and sex (male/female) burden, the observed leukaemia/lymphoma burden was greater for

1 older (versus younger) persons and males (versus females) across both regions. This is in line
2 with other studies exploring patient outcomes in AML, and has been attributed to differences
3 in biological risk factors, lifestyle, or environmental factors, and differences in disease
4 treatment and management [17 18](#). Factors including issues with health systems reporting,
5 differential access to health services between females and males, the interaction between sex
6 and age distribution, and gender inequality have also been implicated in contributing to
7 discrepancies in disease burden between sexes across low-and high-SDI countries [1 5 19](#).
8 However, further studies are recommended to establish and address sex-based drivers of
9 leukaemia/lymphoma burden in countries with low-or-middle SDIs [1 5 10 19](#). The greater
10 burden observed in adults and older age groups also highlights the need for age-period-cohort
11 effect analysis to explore age-specific risk factors and examine the effects of age, time period,
12 and birth cohort on leukaemia/lymphoma incidence and mortality in these regions [20](#).
13 The interaction between factors for differences in leukaemia/lymphoma burden trends
14 between Australasia and Oceanian is similarly complex. First, there are considerable
15 differences in ethnic and genetic distribution across regions. For example, CLL is relatively
16 rare among Pacific Islanders (who comprise the majority of Oceanian populations) compared
17 with Caucasian or European peoples (Australasia) [21](#). Second, the majority of countries in
18 Oceania have limited healthcare infrastructure and access to healthcare specialists, as well as
19 limited access to early detection and advanced medical treatments relative to Australasia [6 22](#).
20 Moreover, although there are several cancer registries in Oceania, the quality and
21 completeness of registration varies [23](#). For example, cancer registries in Fiji have reported
22 cases under-registration, gender miscoding, and variations in coding causes of deaths. Issues
23 regarding the completeness of data and validity of diagnoses have also been reported in
24 Tonga, Cook Islands, and Niue. In the US-affiliated islands such as American Samoa and
25 Guam, there is the potential for missing cases due to historical barriers and the lack of
26 resources for diagnosis and staging [6](#). In contrast, Australasia has well-developed healthcare
27 systems with advanced medical technologies, leading to earlier detection, more effective
28 treatment options and improved survival rates [22](#). Notably, significant reductions in the
29 CML/HL/ALL DALY burden were observed, and NHL DALY burden remained stable over
30 time which reflect improved outcomes due to changes in patient management and treatment
31 across Australasia [24-27](#). However, overall, our findings highlight the need to improve
32 prevention strategies to mitigate exposure to lifestyle factors associated with
33 leukaemia/lymphoma, and the efficient allocation of resources among vulnerable population
34 groups for the treatment for leukaemias/lymphomas [28](#).

1 1 First, while trends were comparable across both sexes; a greater increase in AML mortality
2 2 for males was estimated relative to females. As with disparate disease burden between sexes,
3 3 disparate trends between sexes is consistent with existing studies exploring the
4 4 leukaemia/lymphoma burden for high-SDI countries [1 10](#). That is, differences be attributed to
5 5 differences in tobacco use, occupational exposure to carcinogens and high body mass index
6 6 (BMI) [29](#). Second, the discrepancy between reductions/stable DALY burden (ALL and NHL)
7 7 against increasing mortality/incidence/prevalence over time may highlight disparate
8 8 outcomes across age groups [8 24 25 30](#). ALL follows a bimodal age distribution, with
9 9 incident/prevalent cases peaking during early childhood and later adulthood (≥ 50 years),
10 10 while NHL cases and the risk of mortality (ALL and NHL) increase with age [17 31 32](#).
11 11 Therefore, it is likely that while improved disease management and treatment over time have
12 12 reduced disease burden (DALYs) for younger patients, these changes may not have had an
13 13 equal impact on reducing mortality burden among older patients [24](#). This is supported by
14 14 recent studies exploring ALL and NHL outcomes across Australasia, which found
15 15 improvements in the management or treatment of disease coincided with greater gains in
16 16 survival outcomes for younger relative to older patients [8 24 25 30 33](#). To effectively address the
17 17 ongoing burden of leukaemias/lymphomas, further research should prioritise exploring trends
18 18 in disease burden and treatment outcomes across different age groups, with a focus on
19 19 identifying and addressing the factors contributing to the observed disparities among these
20 20 groups. Although causes of most leukaemias/lymphomas are unknown, general cancer
21 21 prevention strategies can target lifestyle factors, such as avoiding tobacco, having a healthy
22 22 diet, and reducing exposure to hazards such as radiation and toxic chemicals to reduce the
23 23 risk of leukaemias/lymphomas [1](#). Lastly, discrepancies in temporal trends were identified in
24 24 sensitivity analyses using the world standard population. Notably, disease burden attributed
25 25 to AML and NHL reduced across both regions in comparison with base-case estimates. This
26 26 is likely attributed to the variation in population structure in each region, which differs from
27 27 the standard population [3 13](#). As sex and age are associated with cancer outcomes, it is
28 28 possible that EAPCs estimated using the standard population would inadequately capture the
29 29 impact of region-specific differences in age/sex, and ultimately, overestimate patient survival
30 30 trends.

31 31 A key strength of our study lies in using data from the GBD 2019 study, which to date,
32 32 provides the latest regional epidemiological distributions and trends of leukaemias and
33 33 lymphomas [3](#). Besides, the comprehensive analysis of trends across a variety of key outcomes
34 34 facilitates an understanding of the impacts of changes in patient management/treatment on

1 patient outcomes and potential areas of unmet need. Furthermore, disease burden and
2 temporal trends in our study were estimated based on region-specific population, which may
3 better reflect disease burden distribution and trend across age groups and sexes more
4 comprehensively and accurately, particularly when regional population structure is
5 incomparable to the world standard population. Lastly, restricting the analysis to two
6 geographically similar regions with differing SDI, and performing a sensitivity analysis using
7 the world standard population facilitates the comparison of trends between the two regions
8 (base-case), and to other regions or nations at the global level (sensitivity analysis).

9 However, several limitations to our analyses warrant mention. First, this study used data from
10 GBD 2019, which does not include data in 2020 and 2021 (which will be available in the
11 latest GBD update). As a result, it may not capture the most recent trends in disease burden
12 up to 2021. Other limitations associated with GBD 2019 data have been described previously
13 [1-4](#). In brief, it is likely that key outcomes for Oceania were underestimated, as the capacity to
14 collect reliable data on haematological malignancies is often lacking in low-SDI regions.

15 However, this does not considerably change our findings of disparities in disease burden and
16 temporal trends observed between Australasia and Oceania, as well as between male/female
17 sex. Moreover, data variation among the included countries in both regions, such as data
18 quality, accuracy and the degree of missing data, might contribute to the deviation in the
19 estimates, leading to discrepancies between regions [1](#). Second, GBD data includes disease
20 classifications by sex and age groups, but lacks ethnicity data, which limits the analysis of
21 genetic susceptibility to disease. Third, a direct comparison between Australasia and Oceania
22 could be difficult as there are considerable differences in the population distribution and risk
23 factors between the two regions [1-4](#). As such, to explore the potential impacts attributed to age
24 and sex distribution, our analyses used both region-specific populations (base-case) and
25 standard population weights (sensitivity analyses) to explore changes in age-standardised
26 outcomes. Fourth, it was not possible to discern the impact of various exposures on disease
27 outcomes using aggregate data; as such, trends should be interpreted with caution due to
28 potential confounding [1-4](#). Additionally, our EAPC model were limited to detect constant
29 linear trends during the 10-year period. Future research could consider capturing nonlinear
30 trends during this explored period. Moreover, trends of leukaemia/lymphoma burden were
31 predicted based on a single measure, age-standardised rate, for all age groups. This is likely
32 to overlook the differences in trends between children/adolescents and adult population, who
33 might have distinct characteristics and exposures to leukaemias/lymphomas. Lastly, it was

1
2 1 not possible to capture the impacts of the COVID-19 pandemic on leukaemia/lymphoma
3 2 burden using GBD 2019 data [2](#) [3](#) [34](#).
4
5 3 Ultimately, our findings highlight disparities in the management and treatment of
6 4 haematological malignancies based on SDI and sex. Despite the emergence of novel therapies
7 5 and improved treatment/management over time, the consistent and considerable burden of
8 6 AML and NHL in both regions warrants further research to mitigate the gap attributed to
9 7 socioeconomic disadvantage. Further research is also recommended to explore factors that
10 8 contribute to disparate outcomes for sex (male/female).
11
12 9

13 **CONCLUSION**

14 This study captures the disease burden of leukaemias/lymphomas and its temporal trends in
15 two closely situated geographic regions with different SDI. The considerable disparity in
16 disease burden observed between the two regions suggests the need for early diagnosis and
17 better management strategies tailored to each region. Further study is required to explore the
18 underlying factors behind the epidemiological trends of different leukaemia and lymphoma
19 subtypes in each region and the male predominance in the majority of leukaemia and
20 lymphoma burden of disease.

Figures (attached in separate files)

Figure 1 – Age-specific rates at regional level by sex in Australasia and Oceania in 2010 and 2019

Figure 2 - Trends of disease burden based on age-standardised rates in Australasia and Oceania from 2010 to 2019

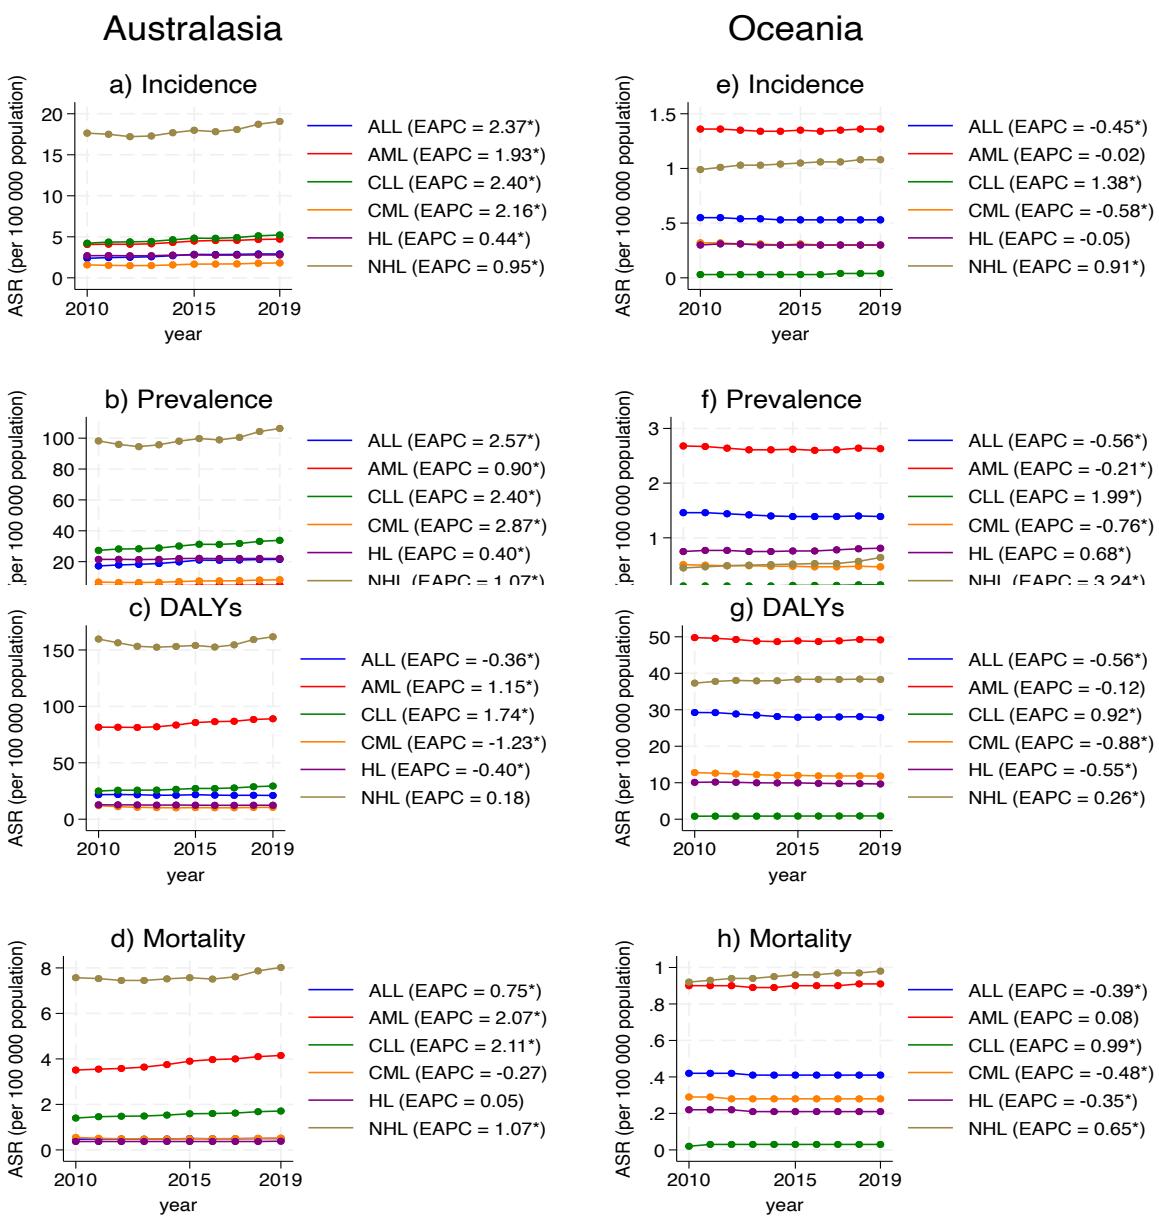

For peer review only

Figure 1. Age-specific rates at regional level by sex in Australasia and Oceania in 2010 and 2019

This figure represents age-specific rates (per 100,000 population) of incidence, prevalence, disability-adjusted life years (DALYs), and deaths in Australasia (a, b, c, d, e, f, g, h), and in Oceania (i, j, k, l, m, n, o, p) by sex in 2010 and 2019, respectively.
 ALL = acute lymphocytic leukaemia; AML = acute myeloid leukaemia; CLL = chronic lymphocytic leukaemia; CML = chronic myeloid leukaemia; DALY = disability-adjusted life year; HL = Hodgkin lymphoma; NHL = non-Hodgkin lymphoma

Figure 2 – Trends of disease burden based on age-standardised rates in Australasia and Oceania from 2010 to 2019

*: statistically significant at 5%; ALL = acute lymphocytic leukaemia; AML = acute myeloid leukaemia; ASR = age-standardised rate; CLL = chronic lymphocytic leukaemia; CML = chronic myeloid leukaemia; DALY = disability-adjusted life year; EAPC = estimated annual percentage change; HL = Hodgkin lymphoma; NHL = non-Hodgkin lymphoma

Appendices

Appendix A

"The International Classification of Diseases (ICD) definition of leukaemias and lymphomas used in the GBD 2019 study has been defined previously¹². ICD codes mapped to the GBD cause list for leukaemia or lymphoma incidence data are as follows: AML (C92.0–C92.02, C92.3–C92.62, C93.0–C93.02, C94.0–C94.02, C94.2–C94.22), ALL (C91.0–C91.02), CML (C92.1–C92.12), CLL (C91.1–C91.12), HL (C81–C81.49, C81.7–C81.79, C81.9–C81.99, Z85.71–Z85.72), and NHL (C82–C85.29, C85.7–C86.6, C96–C96.9)¹². ICD codes mapped to the GBD cause list for leukaemia or lymphoma mortality data are as follows: AML (C92.0, C92.3–C92.6, C93.0, C94.0, C94.2, C94.4–C94.5), ALL (C91.0), CML (C92.1), CLL (C91.1), HL (C81–C81.9), and NHL (C82–C86.6, C96–C96.9)¹².
